## SOLVED EXAMPLES

Ex. 1 Which of the following will be strongest Lewis base ?
(A) $\mathrm{CH}_{3} \mathrm{CN}$
(B) $\mathrm{CH}_{3} \mathrm{NH}_{2}$
(C) $\mathrm{N}_{2}$
(D) None of these

We know that in hybridisation, as s-character increases the electronegativity of atom also increases. Due to this tendency the release of lone pair of electrons becomes some what difficult. In methyl amine the nitrogen is in $\mathrm{sp}^{3}$ hybridisation and therefore the donation of the lone pair of electron will be quite easier; so it is strongest Lewis base.

Ex. 2 Which type of hybridisation is found in $\mathrm{H}_{3} \mathrm{O}^{+}$?
Sol. According to steric no. rule
Steric number $=$ Number of bond pair(s) + number of lone pair(s) at central atom

Thus the hybridisation of oxygen in $\mathrm{H}_{3} \mathrm{O}^{+}$is $\mathrm{sp}^{3}$.

Ex. 3 Classify the following bonds as ionic, polar covalent or covalent and give your reasons :
(A) SiSi bond in $\mathrm{Cl}_{3} \mathrm{SiSiCl}_{3}$
(B) SiCl bond in $\mathrm{Cl}_{3} \mathrm{SiSiCl}_{3}$
(C) CaF bond in $\mathrm{CaF}_{2}$
(D) NH bond in $\mathrm{NH}_{3}$

Sol. (A) Covalent, due to identical electronegativity.
(B) Covalent, due to less electronegativity difference.
(C) Ionic, due to more electronegativity difference.
(D) Covalent, due to nearly similar electronegativity.

Ex. 4 (A) Which one has highest and lowest melting point and why?
NaCl
KCl
RbCl
CsCl
(B) Why melting points of cesium halide ( CsX ) decrease in the order given below?
$\mathrm{CsF}>\mathrm{CsCl}>\mathrm{CsBr}>$ CsI.
Sol. (A) NaCl will have highest lattice energy on account of the smaller $\mathrm{Na}^{+}$while CsCl has lowest lattice energy on account of the larger $\mathrm{Cs}^{+}$. Hence NaCl has highest melting point and CsCl has lowest melting point .
(B) As size of anions increase their polarisability increases thus their covalent character increases and melting point decrease.

Ex. 5 Which is incorrect statement?
(A) In $\mathrm{CF}_{2}=\mathrm{C}=\mathrm{CF}_{2}$ molecule all the four fluorine atoms are not in the same plane.
(B) $\mathrm{Ka}_{2}$ of fumaric acid is more than $\mathrm{Ka}_{2}$ of maleic acid due to intra molecular hydrogen bonding in maleic acid.
(C) The $\mathrm{O}-\mathrm{O}$ bond length in $\mathrm{O}_{2}\left[\mathrm{AsF}_{4}\right]$ is longer than $\mathrm{KO}_{2}$.
(D) The bond angle order in halogen $-\mathrm{S}-$ halogen is $\mathrm{OSF}_{2}<\mathrm{OSCl}_{2}<\mathrm{OSBr}_{2}$

Ans. (C)

Sol. (A)

As both carbon atoms are in different planes, all the four fluorine atoms are not in the same plane. maleic acid

Due to intramolecular hydrogen bonding the maleate ion gets stabilized and thus removal of second hydrogen becomes quite difficult.
(C)

$$
\begin{array}{cc}
\mathrm{O}_{2}\left[\mathrm{AsF}_{4}\right]=\mathrm{O}_{2}^{+} & \mathrm{B} \cdot \mathrm{O}=2.5 \\
\mathrm{KO}_{2}=\mathrm{O}_{2}^{-} & \text {B. } \mathrm{O}=1.5
\end{array}
$$

Bond order $\propto \frac{1}{\text { bond length }} ;$ so $\mathrm{O}_{2}^{+}$has smaller bond length than $\mathrm{O}_{2}^{-}$
(D) Greater the size of the halogen atoms greater will be the steric repulsions and thus larger will be the bond angles.

Ex. 6 Which of the compounds $\mathrm{MgCO}_{3}$ and $\mathrm{ZnCO}_{3}$ is thermally more stable? Explain.
Sol. $\quad \mathrm{Mg}^{+2}$ has less polarising power due to inert gas configuration while $\mathrm{Zn}^{+2}$ has higher polarising power due to pseudo inert gas configuration. A cation i.e. $\mathrm{Zn}^{2+}$ with a greater, polarising power exercise a strong pull on the electron cloud of the neighbouring O -atom of the $\mathrm{CO}_{3}{ }^{2-}$ ion and as such the metal carbonate $\left(\mathrm{ZnCO}_{3}\right)$ gets readily decomposed into $\mathrm{CO}_{2}$ and the oxide of the metal, ZnO . Thus $\mathrm{ZnCO}_{3}$ is less stable than $\mathrm{MgCO}_{3}$.

Ex. 7 Why is anhydrous HCl predominantly covalent in the gaseous state but is ionic in aqueous solution?
Sol. It exists as HCl (bond formed by equal sharing of electrons) but in aqueous solution ionises as $\mathrm{H}^{+}\left(\mathrm{or} \mathrm{H}_{3} \mathrm{O}^{+}\right)$and $\mathrm{Cl}^{-}$ due to polarity of HCl .

Ex. 8 Super oxides are coloured and paramagnetic why?
Sol. Super oxides contain one unpaired electron in anti bonding molecular orbital and are coloured due to transition of HOMO orbital electron within visible region.

## CHEMISTRY

Ex. 9 Of the species $\mathrm{O}_{2}^{+}, \mathrm{O}_{2}^{-}, \mathrm{O}_{2}$ and $\mathrm{O}_{2}^{2-}$ which would have the maximum bond strength ?
Sol. $\quad \mathrm{O}_{2}^{+}$has higher bond order i.e. 2.5 than $\mathrm{O}_{2}(2)$ and $\mathrm{O}_{2}^{-}(1.5)$ and bond strength is directly proportional to bond order.

Ex. 10 Why $\mathrm{BeF}_{2}$ has zero dipole moment whereas $\mathrm{H}_{2} \mathrm{O}$ has some dipole moment?
Sol. $\quad \mathrm{BeF}_{2}$ has linear molecule and $\mathrm{H}_{2} \mathrm{O}$ has bent molecule.

Ex. 11 A diatomic molecule has a dipole moment of 1.2 D. If its bond distance is equal to $1.0 \AA$ then the fraction of an electronic charge on each atom is :
(A) $25 \%$
(B) $37 \%$
(C) $52 \%$
(D) $42 \%$

Ans. (A)
Sol. Assuming complete charge transfer then dipole moment $=\left(4.8 \times 10^{-10} \mathrm{esu}\right)\left(10^{-8} \mathrm{~cm}\right)=4.8 \mathrm{D}$
so $\%$ ionic character $=\frac{1.2}{4.8} \times 100 \%=25 \%$

Ex. 12 Why crystals of hydrated calcium sulphate are soft and easily cleaved where as anhydrous calcium sulphate are very hard and very difficult to cleave?
Sol. With in the $\mathrm{Ca}^{2+} / \mathrm{SO}_{4}^{2-}$ layer the ions are held together by strong electrovalent bonds but these separated $\mathrm{Ca}^{2+} /$ $\mathrm{SO}_{4}{ }^{2-}$ layers are linked by relative weak H -bond. The weak H -bonds link $\mathrm{SO}_{4}{ }^{2-}$ ion in the intermediate region.

Ex. 13 The dipole moment of KCl is $3.336 \times 10^{-29}$ Coulomb meter. The interionic distance in KCl is $2.6 \AA$. Find the $\%$ ionic character in KCl .
Sol. The theoretical dipole moment in $\mathrm{KCl}=\mathrm{e} \times \mathrm{d}=1.602 \times 10^{-19} \times 2.6 \times 10^{-10}=4.1652 \times 10^{-29} \mathrm{C}$ meter
$\%$ ionic character $=\frac{\text { experimental dipole moment }}{\text { theoretical dipole moment }} \times 100=\left(3.336 \times 10^{-29 / 4.1652 \times 10^{-29}}\right) \times 100$

Find the enthalpy of formation (magnitude) of $\mathrm{AX}_{3}(\mathrm{~s})$ in $\mathrm{k} \mathrm{cal} \mathrm{mol}^{-1}$ with the help of the following data. (Non-metal X is found to exist in nature as a diatomic gas)
$\Delta \mathrm{H}_{\text {Sublimation }} \mathrm{A}(\mathrm{s})=100 \mathrm{Kcal} / \mathrm{mol}$
$\Delta \mathrm{H}_{\mathrm{IE}_{1}} \mathrm{~A}(\mathrm{~g})=60 \mathrm{Kcal} / \mathrm{mol}$
$\Delta \mathrm{H}_{\mathrm{IE}_{2}} \mathrm{~A}(\mathrm{~g})=150 \mathrm{Kcal} / \mathrm{mol}$
$\Delta \mathrm{H}_{\mathrm{IE}_{3}} \mathrm{~A}(\mathrm{~g})=280 \mathrm{Kcal} / \mathrm{mol}$
$\Delta \mathrm{H}_{\text {diss }} \mathrm{X}_{2}(\mathrm{~g})=80 \mathrm{Kcal} / \mathrm{mol}$
$\Delta \mathrm{H}_{\text {e.g }} \mathrm{X}(\mathrm{g})=-110 \mathrm{Kcal} / \mathrm{mol}$
$\Delta H_{\text {Lattice energy }} \mathrm{AX}_{3}(\mathrm{~s})=-470 \mathrm{Kcal} / \mathrm{mol}$

Sol.

Ex. 15 CO forms weak bonds to Lewis acid such as $\mathrm{BF}_{3}$. In contrast CO forms strong bonds to transition metals. Why explain ?
Sol. $\mathrm{CO} \longleftarrow \mathrm{BF}_{3}$
Transition metal $\underset{\sigma}{\underset{\sigma}{\underset{~}{\leftrightarrows}}} \mathrm{CO}$
This is called synergic interaction and because of it the bond between CO and transition metal is stronger.

Ex. 16 The gaseous potassium chloride molecule has a measured dipole moment of 10.0 D , which indicates that it is a very polar molecule. The separation between the nuclei in this molecule is $2.67 \times 10^{-8} \mathrm{~cm}$. Calculate the percentage ionic character in KCl molecule.
Sol. Dipole moment of compound would have been completely ionic

$$
=\left(4.8 \times 10^{-10} \mathrm{esu}\right)\left(2.67 \times 10^{-8} \mathrm{~cm}\right)=12.8 \mathrm{D}
$$

$$
\text { so } \% \text { ionic character }=\frac{10.0}{12.8} \times 100 \%=78.125 \% \simeq 78 \% \quad \text { Ans. }

Ex. 17 There will be three different fluorine-fluorine distances in molecule $\mathrm{CF}_{2}(\mathrm{C})_{2} \mathrm{CF}_{2}$. Assuming ideal bond angles for a particular hybridisation (assume no distortion due to double bonds) find out the two smaller fluorinefluorine distances and fill the result (in pm) in the increasing order in your answer sheet. Round off your answer to the nearest whole number.
(Given that $\mathrm{C}-\mathrm{F}$ bond length $=134 \mathrm{pm}, \mathrm{C}=\mathrm{C}$ bond length $=134 \mathrm{pm} \sqrt{3}=1.73$ )

Sol.

$\mathrm{d}_{1}=2 \times 134 \times \sin 60^{\circ} \quad \mathrm{pm}=231.8 \mathrm{pm}=232 \mathrm{pm}$
$\mathrm{d}_{2}=134 \times 3+2 \times 134 \cos 60^{\circ} \mathrm{pm}=536 \mathrm{pm}$ Ans.

Statement-2: Interaction between lone pairs of chloride ions and $\mathrm{Si}^{4+}$ is not very strong and six large chloride ions can not be accommodated around $\mathrm{Si}^{4+}$ due to limitation of its size.
6. Statement-1: In $\mathrm{CH}_{3} \mathrm{NCO}$, the bond angles $\mathrm{C}-\mathrm{N}-\mathrm{C}$ and $\mathrm{N}-\mathrm{C}-\mathrm{O}$ are not identical.

Statement-2: N -atom has a lone pair of electrons which is involved in $\mathrm{p} \pi-\mathrm{d} \pi$ delocalisation where as C -atom does not have lone pair of electrons.
7.

Bond angle R is a normal triangular angle $120^{\circ}$.

Statement-2: $\angle \mathrm{P} \neq 180^{\circ} ; \angle \mathrm{Q} \neq 90^{\circ}$ and thus $\angle \mathrm{R} \neq 120^{\circ}$ but less then $120^{\circ}$ due to the presence of a lone pair.
8. Statement-1: $\mathrm{In}_{\mathrm{IOF}}^{4}-{ }^{-}$a single lone pair is present on iodine atom trans to oxygen atom to have minimum repulsion between the $\mathrm{I}=\mathrm{O}$ and the lone pair of electrons.
Statement-2: The VSEPR model considers double and triple bonds to have slightly greater repulsive effect than single bonds because of the repulsive effect of $\pi$ electrons.
9. Statement-1: Molecules having different hybridisation can have same shape.

Statement-2 : The shape of a molecule does not depend on the hybridisation but it depends on the energy factor.
10. Statement-1: $\mathrm{SO}_{2}, \mathrm{NO}_{3}^{-}$and $\mathrm{CO}_{3}{ }^{2-}$ are isoelectronic as well as isostructural species.

Statement-2: The d and f -orbitals do not shield the nuclear charge very effectively. Therefore, there is significant reduction in the size of the ions, just after $d$ or $f$ orbitals have been completely filled.
11. Statement-1 : $\mathrm{NO}_{3}{ }^{-}$and $\mathrm{PO}_{3}{ }^{-}$have similar formula type but differ structurally i.e. they have different type of hybridisation.

Statement-2 : Nitrogen does not have vacant d-orbital whereas phosphorus have vacant d-orbital.
14. Statement-1: Single $\mathrm{N}-\mathrm{N}$ bond is weaker than the single $\mathrm{P}-\mathrm{P}$ bond.

15. Statement-1: The hybridisation of N atom in acetamide is $\mathrm{sp}^{3}$.

Statement-2 : There occurs delocalisation of lone pair of electrons present on N atom.

16. Statement-1: Cl

Statement-2 : The molecule is T -Shaped and there is repulsion between lone pairs of electrons
17. Statement-1 : The electronic structure of azide ion $\left(N_{3}^{-}\right)$is $[: \underset{\sim}{\sim} \leftarrow N \equiv N:]^{-}$.

Statement-2 : $[\stackrel{\text { N}}{\mathrm{N}=\mathrm{N}:}]^{-}$is not a resonating structure of azide ion, because the position of atoms cannot be changed.
18. Statement-1: $\mathrm{Si}-\mathrm{F}, \mathrm{Si}-\mathrm{C} \ell$ and $\mathrm{Si}-\mathrm{O}$ bonds are stronger than the corresponding bonds with C .

Statement-2 :

20. Statement-1: In graphite, on increasing the temperature the conductivity decreases along the layers of carbon atoms.

## CHEMISTRY

21. Statement-1: A molecule of buckminister fullerene exhibits aromatic character.

Statement-2: Anhydrous $\mathrm{A} \ell \mathrm{C}_{3}$ is electron deficient. The oxygen atom of ether donates a pair of electrons to vacant p -orbital on the $\mathrm{A} \ell$ atom forming a co-ordinate bond.
26. Statement-1: Atomic orbitals are monocentric while molecular orbitals are polycentric.

Statement-2: In an atomic orbital the movement of an electron is influenced by only one positive nucleus, while that of an electron in a molecular orbital is influenced by two or more nuclei depending on the number of atoms contained in the molecule.
27. Statement-1 : To obtain effective $\mathrm{p} \pi-\mathrm{d} \pi$ overlap, the size of the d -orbital must be similar to the size of the $\mathrm{p}-$ orbital. So for chlorine $\mathrm{p} \pi-\mathrm{d} \pi$ bonding is strongest in their oxoanions.
Statement-2: On moving a period from left to right in the periodic table, the nuclear charge is increased and more $s$ and p-electrons are added. Since these s-and p-electrons shield the nuclear charge incompletely, the size of the atom and that of the d -orbitals decreases. This leads to progressively stronger $\mathrm{p} \pi-\mathrm{d} \pi$ bonding.

Statement-2: In $\mathrm{NaHCO}_{3}$ the $\mathrm{HCO}_{3}^{-}$ions are linked together through intermolecular hydrogen bonds into an infinite chain, while in $\mathrm{KHCO}_{3}, \mathrm{HCO}_{3}^{-}$ions form dimeric anions through intermolecular hydrogen bonds.
33. Statement-1: Fluorine $\left(\mathrm{F}_{2}\right)$ is gas while iodine $\left(\mathrm{I}_{2}\right)$ is solid at room temperature.

Statement-2 : A larger molecule or heavy atom is more polarizable and has larger dispersion forces because it has many electrons some of which are less tightly held and are farther from the nucleus.
34. Statement-1: Noble gases are liquefied at very low temperature. Hence they have low boiling points.

Statement-2 : Noble gases being monoatomic have no other interatomic forces except weak dispersion forces.
35. Statement-1: $\mathrm{NF}_{3}$ has little tendency to act as a donor molecule.

Statement-2 : The highly electronegative F atoms attract electrons and these moments partly cancel the moment from the lone pair.
36. Statement-1 : Fluoromethane $\left(\mathrm{CH}_{3} \mathrm{~F} ; \mu=1.85 \mathrm{D}\right)$ has a smaller dipole moment than chloromethane $\left(\mathrm{CH}_{3} \mathrm{Cl} ; \mu=1.87 \mathrm{D}\right)$
Statement-2 : Fluorine has less electron affinity than that of chlorine.
37. Statement-1 : Acetylene is not soluble in $\mathrm{H}_{2} \mathrm{O}$ but is highly soluble in acetone.

Statement-2 : Acetylene forms inter molecular H-bond with acetone easily but not with $\mathrm{H}_{2} \mathrm{O}$ as water molecular themselves are highly associated through inter molecular H -bonds.

## VSEPR Theory

The trigonal bipyramid is not a regular shape since the bond angles are not all the same. It therefore follows that the corners are not equivalent in $\mathrm{ClF}_{3}$ molecule. Lone pairs occupy two of the corners, and F atoms occupy the other three corners. These different arrangements are theoretically possible, as shown in figure.
(i) The most stable structure will be the one of lowest energy, that is the one with the minimum repulsion between the five orbitals. The greatest repulsion occurs between two lone pairs. Lone pair bond pair repulsions are next strongest, and bond pair-bond pair repulsions the weakest.

(1)

(2)

(3)

A rule of thumb can be theorised, that the position having maximum repulsion amongst them are occupied at equatorial points. Therefore (3) structure is right.
(ii) Since double bond occupies more space compared to single bond therefore it will prefer equatorial position.
(iii) More electronegative element will occupy axial position in case of trigonal bipyramidal geometry
(iv) In case of $\mathrm{sp}^{3} \mathrm{~d}^{2}$ hybridisation lone pairs should be placed opposite to each other because all the corners are identical.

## Comprehension \# 2

The distribution of electrons among various molecular orbitals is called the electronic configuration of the molecule which provides us the following very important informations about the molecule .
(A) Stability of molecule : The molecule is stable if number of bonding molecular orbital electrons $\left(\mathrm{N}_{\mathrm{b}}\right)$ is greater than the number of antibonding molecular orbital electrons $\left(\mathrm{N}_{\mathrm{a}}\right)$ and vice- versa.
(B) Bond order :

Bond order $=\frac{1}{2}\left(\mathrm{~N}_{\mathrm{b}}-\mathrm{N}_{\mathrm{a}}\right)$
A positive bond order means a stable molecule while a negative or zero bond order means an unstable molecule.
(C) Nature of the bond :

Bond order 1, 2, or 3 corresponds to single, double or triple bonds respectively.
(D) Bond length :

Bond length decreases as bond order increases.
(E) Magnetic nature :

Molecular orbitals in a molecule are doubly occupied, the substance is diamagnetic and if one or more molecular orbitals are singly occupied, it is paramagnetic.

1. Which of the following statements is incorrect?

(B) the difference in energy ( $\Delta \mathrm{E}$ ) between HOMO and LUMO is small and the electronic excitation take place by absorption of light which falls in infrared region.
(C) the bromine molecule is paramagnetic and the difference in energy $(\Delta \mathrm{E})$ is such that the electronic excitation take place in visible light.
(D) the difference in energy ( $\Delta \mathrm{E}$ ) between HOMO and LUMO is such that the electronic excitation take place by absorption of light which falls in visible region and bromine molecule is diamagnetic.
3. $\quad \mathrm{N}_{2}$ has greater bond dissociation energy than $\mathrm{N}_{2}^{+}$, where as $\mathrm{O}_{2}$ has a lower bond dissociation energy than $\mathrm{O}_{2}^{+}$ because:
(A) Bond order is reduced when $\mathrm{O}_{2}$ is ionized to $\mathrm{O}_{2}^{+}$and bond order is increased when $\mathrm{N}_{2}$ is ionized to $\mathrm{N}_{2}^{+}$
(B) Bond order is increased when $\mathrm{O}_{2}$ is ionized to $\mathrm{O}_{2}^{+}$and bond order is decreased when $\mathrm{N}_{2}$ is ionized to $\mathrm{N}_{2}{ }^{+}$
(C) Bond order is deceased when $\mathrm{O}_{2}$ is ionized to $\mathrm{O}_{2}^{+}$and bond order is decreased when $\mathrm{N}_{2}^{-}$is ionized to $\mathrm{N}_{2}^{+}$
(D) None of these.

## Comprehension \# 3

A covalent bond in which electrons are shared unequally and the bonded atoms acquire a partial positive and negative charge, is called a polar covalent bond. Bond polarity is described in terms of ionic character.
Similarly in ionic bond, some covalent character is introduced because of the tendency of the cation to polarise the anion. The magnitude of covalent character in the ionic bond depends upon the extent of polarization caused by cations.

In general :
(i) Smaller the size of cation, larger is its polarizing power.
(ii) Larger the anion, more will be its polarisability.
(iii) Among two cations of similar size, the polarizing power of cations with pseudo - inert gas configuration $\left(n s^{2} n p^{6} n d^{10}\right)$ is larger than cation with noble gas configuration $\left(n s^{2} n p^{6}\right)$ e.g. polarizing power of $\mathrm{Ag}^{+}$is more than $\mathrm{K}^{+}$.

## Comprehension \# 4

The degree of polarity of a covalent compound is measured by the dipole moment ( $\mu_{\text {bond }}$ ) of the bond defined as:
$\mu_{\text {bond }}=$ Charge on one of the poles $\times$ bond length
$\mu_{\text {bond }}$ is a vector quantity. The dipole moment of a molecule is the vector addition of all the bond dipole moments present in it. For a triatomic molecule, containing two bond's like $\mathrm{H}_{2} \mathrm{O}, \mu_{\text {molecule }}$ is given by

$$
\begin{aligned}
& \mu_{\text {molecule }}^{2}=\mu_{\text {bond }}^{2}+\mu_{\text {bond }}^{2}+2 \mu_{\text {bond }} \cdot \mu_{\text {bond }} \cos \theta \\
& \theta=\text { bond angle }
\end{aligned}
$$

The \% ionic character of a bond is calculated using the equations

$$
\% \text { ionic character }=\frac{\mu_{\text {obs }}}{\mu_{\text {ionic }}} \times 100
$$

$\mu_{\text {ionic }}=$ dipole moment when the molecule is assumed to be completely ionic.

## Comprehension \# 5

Molecular geometry is the general shape of a molecule as determined by the relative positions of the atomic nuclei. VSEPR model predicts the shape of the molecules \& ions in which valence shell electron pairs are arranged about the atom as far away from one another as possible, thus minimizing pair repulsion information about the geometry of a molecule can sometimes be obtained from an experimental quantity called dipole moment.

## Comprehension \# 6

Nitrogen, oxygen and fluorine are the highly electronegative elements. When they are tied to a hydrogen atom to form covalent bond, the electrons of the covalent bond are shifted towards the more electronegative atom. This partially positively charged hydrogen atom forms a bond with the other electronegative atom. This bond is called as hydrogen bond and is weaker than covalent bond. For example, in HF molecule, the hydrogen bond exists between hydrogen atom of one molecule and fluorine atom of another molecule as depicted :--- $\mathrm{H}^{\delta+}-\mathrm{F}^{\delta-}---\mathrm{H}^{\delta+}-\mathrm{F}^{\delta-}--$ $-\mathrm{H}^{\delta+}-\mathrm{F}^{\delta-}$
Here, hydrogen bond acts as a bridge between atoms which holds one atom by covalent bond and the other by hydrogen bond. Hydrogen bond is represented by a dotted line ( --- ) while a solid line represents the covalent bond. Thus, hydrogen bond can be defined as the attractive force which binds hydrogen atom of one molecule with the electronegative atom ( $\mathrm{F}, \mathrm{O}$ or N ) of another molecule.

When anions and cations approach each other, the valence shell of anions are pulled towards a cation, is known as polarisation and ability of a cation to polarize the anion is called as polarising power of cation. Due to polarisation, sharing of electrons occurs between two ions to some extent and bond shows some covalent character. Fajan's suggested following factors on which polarisation depend.
(i) As the charge on cation or anion increases polarisation increases.
(ii) Size of cation decreases or size of anion increases, polarisation increases.
(iii) Cation with pseudo noble gas configuration shows higher polarisation power than that with inert gas configuration.
21. Arrange the following compounds in increasing order of covalent character.

## Comprehension \# 2

The distribution of electrons among various molecular orbitals is called the electronic configuration of the molecule which provides us the following very important informations about the molecule.
(A) Stability Of molecule : The molecule is stable if number of bonding molecular orbital electrons $\left(\mathrm{N}_{\mathrm{b}}\right)$ is greater than the number of antibonding molecular orbitals electrons $\left(N_{a}\right)$.

A positive bond order means a stable molecule while a negative or zero bond order means an unstable molecule.
(C) Nature of the Bond: Bond order 1, 2 and 3 corresponds to a single, double and triple bond respectively.
(D) Bond Length : Bond length decreases as bond order increases
(E) Magnetic Nature : Molecular orbitals in a molecule are doubly occupied, the substance is diamagnetic and if one or more molecular orbitals are singly occupied, it is paramagnetic.
