

modern physics: rest imp questions(solutions)

Explanations

- (Laws of Photoelectric Emission)
- 2. Intensity It is the number of photons passing through an area in a given interval of time. Its SI unit is watt/metre². (1)
- 3. Variation of photoelectric current versus potential for different intensities and equal frequencies.

4. The intensity of radiation is defined as the rate of emitted energy from unit surface area in a given interval of time.

Its SI unit is watt/metre².

be the work function.

5. Metal A has higher value of work function because the intercept of the line of the given graph depends on work function. Thus, higher the intercept of the graph higher will

(1)

(1)

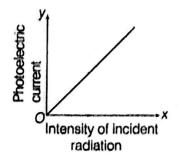

(1)

As OQ > OP $V_0 \qquad Metal \ B \ Metal \ A$ $O \ P \ Q \qquad V_0 \qquad V_0$

- So, the threshold frequency of metal A is greater than metal B.
- 7. Photoelectric effect is a one-photon-one electron phenomenon. Therefore, when the intensity of radiation incident on the surface increases, the number of photons per unit area unit time increases (since the intensity of incident radiation ≈ number of photons). Hence, the photoelectrons ejected will be large, which in turn, will contribute to the increase in photoelectric current. (1)

- while curves 3 and 4 represent different materials, since the value of stopping potential for the pair of curves (1 and 2) and (3 and 4) are the same. For given frequency of the incident radiation, the stopping potential is independent of its intensity.

 So, the pairs of curves (1 and 3) and (2 and 4) correspond to different materials but same intensity of incident radiation.
- Graph of variation of photoelectric current with the intensity of incident radiation on a photosensitive surface is given as alongside.

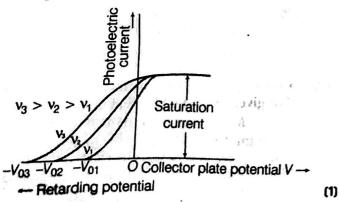

10. Photoelectric emission is not possible at all frequencies because below the threshold frequency for photosensitive surface of different atoms emission is not possible. (1)

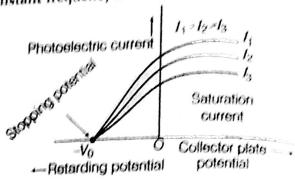

(1)

- 11. Threshold frequency does not depend upon the intensity of light. The intensity of light mainly depends on the number of photons for given frequency of incident radiation. Therefore, the photoelectric current increases with the intensity of incident light.

 (1)
- 12. In experimental set up of photoelectric effect, the value of negative potential of anode at which photoelectric current in the circuit reduces to zero is called stopping potential or cut-off potential for the given frequency of the incident radiation. (1)
- **13.** The variation of photoelectric current with collector plate potential for different plate frequencies is shown as below:

14. The variation of photoelectric current with collector plate potential for different intensities at constant frequency is shown as below:

- - (i) The greater energy incident per u t time per unit area increases with the increase of intensity which should facilitate liberation of photoelectron of greater kinetic energy which is in contradiction of observed feature of photoelectric effect.
 - (ii) Wave theory states that energy carried by wave is independent of frequency of light wave and hence wave of high intensity and low frequency (less than threshold frequency) should stimulate photoelectric emission but practically, it does not happen.

Considering the following few properties of photon, the above problem was resolved.

- (i) In interaction of radiation with radiation behaves as if it is made up of particle called photon.
- (ii) Energy of a photon is directly proportional to the frequency of the incident light.
- **16.** Two salient features observed in photoelectric effect and their explanation on the basis of Einstein's photoelectric equation is given as below
 - (i) Threshold frequency For $KE_{max} \ge 0$.

$$\Rightarrow$$
 $v \ge v_0$

i.e. the phenomenon of photoelectric effect takes place when incident frequency is greater or equal to a minimum frequency (threshold frequency) v_0 fixed for given metal.

(ii) Effect of intensity of incident light The number of photons incident per unit time per unit area increases with the increase of intensity of incident light. More number of photons facilitates ejection of more number of photoelectrons from metal surface leads to further increase of photocurrent till its saturation value is reached.

7. (a) Refer to text on page 341 and Sol. 12 on page 350.

(b) Refer to Sol. 3 on page 349 (1) (1)

Given,
$$\lambda = 412.5 \,\text{nm} = 412.5 \times 10^{-9} \,\text{m}$$

$$E = \frac{hc}{\lambda} = \frac{6.63 \times 10^{-34} \times 3 \times 10^8}{412.5 \times 10^{-9} \times 1.6 \times 10^{-19}} \text{ eV}$$
$$= 301 \text{ eV}$$

(1) From the given question, work function (4) of the following metals are given as

Na
$$\rightarrow$$
 1.92, K \rightarrow 2.15
Ca \rightarrow 3.20, Mo \rightarrow 4.17

As the given energy is greater than the work function of Na and K only, hence these metals shows photoelectric emission.

19. Given, V = 3.3 V and frequency of photons $(v) = 8 \times 10^{14} \text{ Hz}$

As we know,

$$eV_0 = hv - \phi$$

$$\phi = hv - eV_0$$

$$\Rightarrow \phi(eV) = \frac{6.63 \times 10^{-34} \times 8 \times 10^{14}}{1.6 \times 10^{-19}} \text{ eV} - 33 \text{ eV}$$

$$= (3.31 - 3.3) \text{ eV}$$

$$\phi = 0.01 \text{ eV}$$
(2)

20. Given, frequency, $f = 6.0 \times 10^{14} \text{ Hz}$

Power, $P = 2.0 \times 10^{-3} \text{ W}$

(i) Energy of emitted photons, E = hv $=6.63\times10^{-34}\times6\times10^{14}$ $= 4 \times 10^{-19} \text{ J}$

(ii) Number of photons emitted per second,

$$n = \frac{P}{E} = \frac{2 \times 10^{-3}}{4 \times 10^{-19}} = 5 \times 10^{15} \text{ photons}$$
(1)

21. For a given frequency, intensity of light in the

photon picture is determined by
$$I = \frac{\text{Energy of photons}}{\text{area} \times \text{time}} = \frac{n \times hv}{A \times t}$$

where, n is the number of photons incident (2) normally on crossing area A in time t.

22. Using Einstein's photoelectric equation,

$$eV = hv - \phi_0$$

On differention, we get $e\Delta V = h\Delta v$

On differention, we get
$$e\Delta V = h\Delta V$$

or $h = \frac{e\Delta V}{\Delta V} = \frac{1.6 \times 10^{-19} \times (1.23 - 0)}{(8 - 5) \times 10^{14}}$

$$= 6.56 \times 10^{-34} \text{ J-}$$
 (2)

23. (i) Refer to Sol. 20

(1) (ii) Refer to Sol. 9

OR (1)

(i) 1015 photons; Refer to Sol. 20 (1)

(ii) Refer to Sol. 9

(1)

(1)

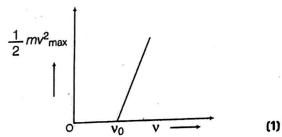

24. Three basic properties of photons are given as below (i) Photons are quanta or discrete carriers of energy.

(ii) Energy of a photon is proportional to the frequency of light.

(iii) The photon gives all its energy to the electron (1) with which it interacts. Einstein's photoelectric equation

$$\frac{1}{2}mv_{\max}^2 = hv - \phi_0$$

The plot is shown as below

(1)25. (i) Refer to Sol. 12

(1) (ii) Refer to Sol. 13

26. (i) For a given material, there exists a certain minimum frequency of the incident radiation below which no emission of photoelectrons take place. This frequency is called the (1) threshold frequency.

(1) (ii) Refer to Sol. 3

27. (i) Intensity of incident radiation, I = nhv, where nis number of photons incident per unit time per unit area, h is Planck's constant and v is frequency of photon.

For same intensity of two monochromatic radiations of frequencies v₁ and v₂ $n_1 h v_1 = n_2 h v_2$

As,
$$v_1 > v_2$$
 and $n_2 > n_1$ (1)

Therefore, the number of electrons emitted for monochromatic radiation of frequency v_2 , will be more than that for radiation of frequency v_1 .

(ii) As, $hv = \phi_0 + KE_{max}$

 \therefore For given ϕ_0 (work function of metal)

 K_{max} increases with v

.. Maximum kinetic energy of emitted photoelectron will be more for monochromatic light of frequency v_1 (as $v_1 > v_2$). (1)

- 28. The intensities for both the monochromatic radiation are same but their frequencies are different. Thus,
 - (i) The number of electrons ejected in two cases are same because it depends on the number of incident photons.
 - (ii) As, $KE_{max} = hv \phi_0$ [Einstein's photoelectric current]

$$\Rightarrow KE_{max} \propto V$$

Since, $v_{violet} > v_{blue}$

:. The KE_{max} of violet radiation will be more. (1)

29. Einstein's photoelectric equation,

$$KE_{max} = hv - \phi_0 \qquad ...(i)$$

(1)

(1)

where, v = frequency of incident light beam

 ϕ_0 = work function of metal

 $KE_{max} = maximum kinetic energy$

$$\phi_0 = h v_0$$

where, v_0 is threshold frequency.

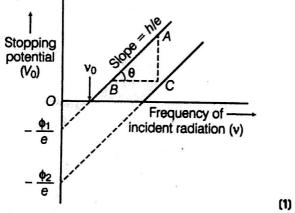

$$\Rightarrow KE_{\max} = hv - hv_0$$

$$\Rightarrow KE_{\max} = h(v - v_0) \qquad ...(ii) (1)$$

This equation is obtained by considering the particle nature of electromagnetic radiation.

For salient features Refer to Sol. 16 on page 350.

30. The variation of stopping potential with frequency of incident radiation is shown as below:

- (i) The slope of stopping potential versus frequency of incident radiation gives the ratio of Planck's constant (h) and electronic charge (e).
- (ii) Intercept on the frequency axis gives the value of threshold frequency v_0 .

Intercept on the potential axis =
$$-\frac{hv_0}{e}$$
 (1/2)

21. Einstein's photoelectric equation Refer to text on page 342.

From Einstein photoelectric equation

$$KE_{max} = hv - \phi \Rightarrow \frac{m}{2}v_{max}^2 = hv - \phi$$

$$\Rightarrow v_{\max}^2 = \frac{2h}{m} v - \frac{2\phi}{m} \cdots (i)$$

As we know that, the equation of straight line

$$y = mx + c$$
 ···(ii)

where, m is the slope of the line.

By comparing Eq. (i) with Eq. (ii), we get

$$m = \frac{2h}{m}$$
 and $c = \frac{-2\phi}{m}$

$$\Rightarrow \tan\theta = \frac{2h}{m} \Rightarrow h = \frac{m \tan \theta}{2}$$

and l (from graph) $l = c = \frac{-2\phi}{m}$

$$n = \frac{\phi}{h}\Big|_{v_{\text{max}} = 0} \qquad [\text{from Eq. (i)}]$$

32. (i) From Einstien's photoelectric equation, we have

$$K_{\text{max}} = h \mathbf{v} - \phi_0$$

where, K_{max} is maximum kinetic energy of the photoelectrons, ϕ_0 is work function and hv is energy of the incident photon.

As
$$K_{\text{max}} \ge 0$$

So, $hv - \phi_0 \ge 0$ or $v \ge \frac{\phi_0}{h}$

Thus, photoemission occurs, when frequency is greater than threshold frequency, $v \ge \frac{\phi_0}{h}$. (1%)

(ii) Energy of the incident radiation of wavelength λ

$$E = \frac{hc}{\lambda} = \frac{(6.63 \times 10^{-34}) \times (3 \times 10^{8})}{3300 \times 10^{-10} \times 1.6 \times 10^{-19}} = 3.76 \text{ eV}$$

This energy of the incident radiation is greater than the work function of Na and K but less than those of Mo and Ni, so photoelectric emission will occur only in Na and K metals and not in Mo and Ni.

If the laser is brought closer, the intensity of incident radiation increases. This does not affect the result regarding Mo and Ni metals, while photoelectric current from Na and K will increase in proportion to intensity. (1½)

33. (i) Einstein's photoelectric equation is

$$eV_0 = K_{\text{max}} = hv - \phi_0$$

Important features of this equation are given below:

 (a) Photoemission occurs when frequency of incident radiation is more than the threshold frequency, v≥ [♠]0

- (b) Energy of emitted photoelectron is proportional to energy of incident photon.
- (ii) Energy of incident photon is less than work function of P but just equal to that of Q.

Work function,
$$\phi_0 = \frac{hv}{e}(eV)$$

$$= \frac{6.6 \times 10^{-14} \times 10^{15}}{1.6 \times 10^{-19}} = 4.1 \text{ eV}$$
(1%)

4. (i) Einstein's photoelectric equation

$$hV = \phi + eV$$

$$V = \frac{hV}{e} = \frac{\phi}{e} \qquad \dots (1)$$

where, h is Planck's constant.

gq. (i) represents a straight line given by line P and Q $\frac{\Phi}{g}$ represents negative intercept on the

y-axis. Since, Qhas greater negative intercept, it will have greater ϕ (work function) and hence higher threshold frequency. (1)

(ii) To know work function of Q we put $V \approx 0$ in the Eq. (i),

$$0 = \frac{h\mathbf{v}}{c} - \frac{\phi}{e}$$

$$\Rightarrow \quad \phi = h\mathbf{v}$$

$$\therefore \quad \phi = 6.6 \times 10^{-34} \times 6 \times 10^{14} \text{ J}$$

$$(\because \text{ Planck's constant, } h = 6.6 \times 10^{-34})$$

$$= \frac{6.6 \times 6 \times 10^{-20}}{1.6 \times 10^{-19}} \text{ eV}$$

$$= 2.5 \,\mathrm{eV} \tag{1}$$

(iii) From the equation $v\lambda =$

$$\lambda = \frac{c}{v} = \frac{3 \times 10^8}{8 \times 10^{14}} = \frac{30}{8} \times 10^{-7} \text{m}$$
$$= \frac{30}{8} \times 10^3 \times 10^{-10} \text{m}$$
$$= \frac{30}{8} \times 10^3 \,\text{Å} = 3750 \,\text{Å}$$
$$= 12375 - 12375 \,\text{eV}$$

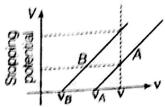

Energy =
$$\frac{12375}{\lambda(\text{Å})} = \frac{12375}{3750} \text{ eV}$$

= 33 eV

Maximum KE of emitted electron = 33 - 2.5 eV $= 0.8 \, \text{eV}$ (1)

We know,
$$K_{\text{max}} = eV = h(v - v_0)$$

or $V = \frac{h}{e}v - \frac{h}{e}v_0$

(i) From the graph for the same value of ${f v}$, stopping potential is more for material B.

As,
$$V = \frac{h}{c}(v - v_0)$$

 \therefore V is higher for lower value of \mathbf{v}_0 . Here $V_B < V_A$, so $V_B > V_A$.

(2)

(1)

(ii) Slope of the graph is given by h/e which is constant for all the materials. Hence, slope of the graph does not depend on the nature of (1)the material used.

36. Refer to Sol. 9 on page 350.
Given that,
$$\lambda = 3300 \times 10^{-10} \,\text{m}$$
,

$$\phi_{Na} = 2.75 \text{ eV}, \phi_{Mis} = 4.175 \text{ eV}.$$

Then energy of the laser beam is

$$E = \frac{hc}{\lambda} = \frac{6.6 \times 10^{-34} \times 3 \times 10^{4}}{3300 \times 10^{-10} \times 1.6 \times 10^{-19}} = 3.75 \text{ eV}$$

Since, $E < \phi_{Mo}$ therefore there will be no emission of photoelectrons for molybdenum (Mo).

Bringing the source nearer will cause to emit more photoelectrons as intensity on the plate will increase. (2)

37. Refer to Sol. 1 on page 349. (1) Given that threshold frequency of metal is v and frequency of light is 2v. Using Einstein's equation for photoelectric effect, we can write

$$h(2v - v) = \frac{1}{2}mv_1^2$$
 ... (i)

Similarly, for light having frequency 5v, we have

$$h(5v - v) = \frac{1}{2}mv_2^2$$
 ... (ii)

Using Eqs. (i) and (ii), we get

$$V/4V = v_1^2/v_2^2 \implies v_1/v_2 = \sqrt{1/4} \implies v_1/v_2 = 1/2$$

38. Einstein's photoelectric equation is given below:

$$hv = \frac{1}{2}mv_{\text{max}}^2 + \phi_0$$

where, v = frequency of incident radiation $\frac{1}{2}mv_{\text{max}}^2 = \text{maximum kinetic energy of an emitted}$

$$\phi_0$$
 = work function of the target metal (1)

Three salient features observed are

- (i) Below threshold frequency v_0 corresponding to ϕ_0 , no emission of photoelectrons takes place.
- (ii) As energy of a photon depends on the frequency of light, so the maximum kinetic energy with which photoelectron is emitted depends only on the energy of photon or on the frequency of incident radiation.
- (iii) For a given frequency of incident radiation, intensity of light depends on the number of photons per unit area per unit time and one photon liberates one photoelectron, so number of photoelectrons emitted depend only on its intensity.
- 39. (i) Important properties of photons which are used to establish Einstein's photoelectric equations.
 - (a) In interaction of radiation with matter, radiation behaves as, if it is made up of particles called photons.
 - (b) Each photon has energy $E (= hv = hc/\lambda)$ and momentum $p(=hv/c=h/\lambda)$, where c is the speed of light, h is Planck's constant, ν and λ are frequency and wavelength of radiation respectively.
 - (c) All photons of light of a particular frequency v or wavelength λ have the same energy $E (= hv = hc/\lambda)$ and momentum $p = hv/c = h/\lambda$ whatever the intensity of radiation may be. $(1\frac{1}{2})$
 - (ii) Since, Einstein's photoelectric equation is given by

$$KE_{max} = \frac{1}{2}mv_{max}^2 = hv - h\phi_0$$

- (a) For a given material, there exist a certain minimum frequency of the incident radiation below, which no emission of photoelectron takes place. This frequency is called threshold frequency. Above threshold frequency, the maximum kinetic energy of the emitted photoelectron or equivalent stopping potential independent of the intensity of the incident light but depends only upon the frequency of the incident light.
- (b) If the collecting plate in the photoelectric apparatus is made at high negative potential, then most of the high energetic electrons get repelled back along the same path and the photoelectric current in the circuit becomes zero. So, for a particular frequency of incident radiation, minimum negative potential for which the electric current becomes zero is called cut-off or stopping potential.

- 40. (1) Three experimentally observed features in the phenomenon of photoelectric effect is
 - (a) Intensity When intensity of incident light increases as one photon ejects one electron, the increase in intensity will increase the number of ejected electrons Frequency has no effect on photoelectron
 - (b) Frequency When the frequency of incident photon increases, the kinetic energy of the emitted electrons increases Intensity has no effect on kinetic energy of photoelectron.
 - (c) No time lag When energy of incident photon is greater than the work function. the photoelectron is immediately ejected Thus, there is no time lag between the incidence of light and emission of photoelectron. (1/2 × 3)

For two features, Refer to Sol. 15 on page 350.

(ii) Also, according to the wave theory, the absorption of energy by electron takes place continuously over the entire wavefront of the radiation.

Hence, it will take hours or more for a single electron to come out of the metal which contradicts the experimental fact that photoelectron emission of instantaneous(1/2 x 3)

41. Einstein's photoelectric equation

$$K_{\text{max}} = \frac{1}{2}mv^2 = hv - \phi_0 = hv - hv_0$$
 ... (i)

For important features,

From Eq. (i),

$$K_{\max} = \frac{hc}{\lambda} - \phi_0$$

According to question,
$$K_{\text{max}} = \frac{hc}{\lambda_1} - \phi_0 \qquad \dots \text{ (ii)}$$

(1)

(1)

$$2K_{\text{max}} = \frac{hc}{\lambda_2} - \phi_0 \qquad \dots \text{ (iii)}$$

From Eqs. (ii) and (iii),

$$2\left(\frac{hc}{\lambda_{1}} - \phi_{0}\right) = \frac{hc}{\lambda_{2}} - \phi_{0}$$

$$\phi_{0} = \frac{2hc}{\lambda_{1}} - \frac{hc}{\lambda_{2}}$$

$$= hc\left(\frac{2}{\lambda_{1}} - \frac{1}{\lambda_{2}}\right)$$
Also,
$$\phi_{0} = \frac{hc}{\lambda_{0}}$$

$$\frac{hc}{\lambda_0} = hc \left(\frac{2}{\lambda_1} - \frac{1}{\lambda_2} \right)$$
or
$$\frac{1}{\lambda_0} = \frac{2\lambda_2 - \lambda_1}{\lambda_1 \lambda_2}$$

$$\lambda_0 = \frac{\lambda_1 \lambda_2}{2\lambda_2 - \lambda_1}$$
(1)

- (i) Yes, all emitted photoelectrons have same kinetic energy as the kinetic energy of emitted photoelectrons depending upon frequency of the incident radiation for a given photosensitive surface.
 - (ii) No, the kinetic energy of emitted electrons does not depend on the intensity of incident radiation. If the intensity is increased, number of photons will also increase but energy of each photon remains same as the frequency is also same. The maximum kinetic energy depends on frequency not on intensity.
 - (iii) The number of emitted photoelectrons depends only on intensity of incident light. (1)
- 43. For Einstein equation Refer to Sol. 41

properties of photons Refer to 39(i)

 $(1\frac{1}{2})$

2111

For these observed features Refer to Sol. 39

- 44. (i) For three important properties of photon, refer to Sol. 39 (i) (1½)
 - (ii) Refer to Sol. 39 (ii) (1½)
- 45. (i) The photoelectric effect cannot be explained on the basis of wave nature of light because wave nature of radiation cannot explain the following
 - (a) The instantaneous ejection of photoelectrons.
 - (b) The existence of threshold frequency for a metal surface.
 - (c) The fact that kinetic energy of the emitted electrons is independent of the intensity of light and depends upon its frequency. (1½)
 - (ii) Photon picture of electromagnetic radiation on which Einstein's photoelectric equation is based on particle nature of light. Its basic features are given as below:
 - (a) In interaction of radiation with matter, radiation behaves as if it is made up of particles called photons.

- (b) Each photon has energy $E\left(=hv=\frac{hc}{\lambda}\right)$ and momentum $p\left(=\frac{hv}{c}=\frac{h}{\lambda}\right)$ where, c is the speed of light, h is Planck's constant, v and λ are frequency and wavelength of radiation, respectively.
- (c) All photons of light of a particular frequency v or wavelength λ have the same energy $E\left(=hv=\frac{hc}{\lambda}\right)$ and momentum

$$p\left(=\frac{hv}{c} = \frac{h}{\lambda}\right)$$
 whatever the intensity of radiation may be. (11/2)

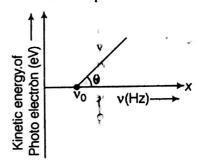

46. Kinetic energy of photoelectrons emitted from the surface of a photosensitive material,

$$KE = hv - \phi = hv - hv_0$$

This is an equation of straight line of the form,

$$y = mx + c (1)$$

(i) From this graph, the Planck's constant can be calculated by the slope of the line. (1)

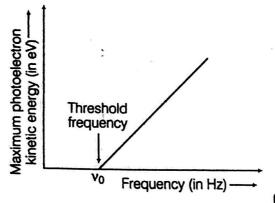

- (ii) Work function is the minimum energy required to eject the photo-electron from the metal surface.
 - $\phi = hv_0$, where v_0 = threshold frequency From the graph, work function is given by intercept of line on the kinetic energy axis.
- 47. The two characteristic features observed in photoelectric effect which support the photon pictures of electromagnetic radiation are given as below:
 - (a) All photons of light of a particular frequency v or wavelength λ have the same energy

$$E\left(=hv=\frac{hc}{\lambda}\right) \text{ and momentum, } p\left(=\frac{h}{\lambda}\right)$$

whatever the intensity of radiation may be.

(b) Photons are electrically neutral and not deflected by electric and magnetic fields.

(1)

(i) Planck constant is given by the slope of the curve,

i.e. Slope of graph = $\frac{h}{e}$

(ii) Work function is the minimum energy required by the electron to escape out of the metal surface thus,

$$\phi = h v_0$$

Here, v_0 is the threshold frequency.

- .. From the given graph, work is given by intercept of the line on the kinetic energy axis.
- **48.** Refer to Sol. 29

and Sol. 38

(3)

49. Cut-off voltage The minimum negative voltage (V_0) applied on anode plate w.r.t, the cathode for which photocurrent in the circuit reduces to zero.

For threshold frequency Refer to Sol. 1 on page 349.

Einstein's equation, $hv = KE_{max} + \phi_0$

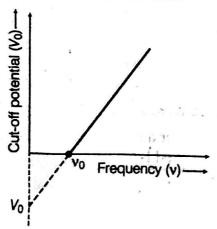

$$hv = KE_{\text{max}} + hv_0 \quad [\because \phi_0 = hv_0]$$

$$KE_{\text{max}} = hv - hv_0$$

$$eV_0 = hv - hv_0 \quad [\because KE_{\text{max}} = eV_0]$$

$$V_0 = \frac{h}{e} (v - v_0)$$

The variation of cut-off potential with frequency of incident radiation is shown as below.

From this graph, the value of threshold frequency is given by the point of intersection of the straight on the frequency axis and stopping potential is given by the point of intersection of the straight line on potential axis, i.e. the intercept of the line on cut-off potential axis.

50.
$$\lambda = 2000 \text{ Å} = 2000 \times 10^{-10} \text{ m}, \, \phi_0 = 4.2 \text{ eV}$$

$$h = 6.63 \times 10^{-34} \text{ J-s}$$

$$\frac{hc}{\lambda} = \phi_0 + \text{KE}$$

$$\Rightarrow \text{KE} = \frac{hc}{\lambda} - \phi_0$$

$$= \frac{(6.63 \times 10^{-34}) \times (3 \times 10^8)}{(2000 \times 10^{-10})}$$

$$\times \frac{1}{1.6 \times 10^{-19}} \text{ eV} - 4.2 \text{ eV}$$

$$= (6.2 - 4.2) \text{ eV} = 2.0 \text{ eV}$$

- (i) The energy of the emitted electrons does no depend upon intensity of incident light hence the energy remains unchanged.
- (ii) For this surface, electrons will not be emitted as the energy of incident light (6.2 eV) is less than the work function (6.5 eV) of the surface.
- 51. For plot Refer to Sol. 13

By Einstein's photoelectric equation

$$V_0 = \left(\frac{h}{e}\right) v - \frac{\phi_0}{e} \qquad \dots (i)$$

where,

 $V_0 = \text{cut-off potential}$

h = Planck's constant

e =electronic charge

 ϕ_0 = work function of material

It is clear that for higher frequency v, cut-off potential is higher.

- .. Stopping potential will be higher corresponding to frequency v_2 .
- **52.** (i) Einstein's photoelectric equation is

$$KE_{max} = hv - \phi_0$$

But, where,

$$KE_{max} = eV_0$$

 $V_0 = \text{cut-off potential} = 1.3 \text{ V}$

$$eV_0 = hv - \phi_0 \implies \phi_0 = hv - eV_0$$

Here, $h = 6.63 \times 10^{-34} \text{ J}_{-8}$

$$\lambda = 2271 \text{ Å} = 2271 \times 10^{-10} \text{ m}$$

$$v = \frac{c}{\lambda} = \frac{3 \times 10^8}{2271 \times 10^{-10}}$$

$$eV_0 = 1.6 \times 10^{-19} \times 1.3 = 2 \times 10^{-19}$$

$$\therefore \text{ Work function,} = hv - eV_0$$

$$= (6.63 \times 10^{-34}) \times (1.32 \times 10^{15}) - 2 \times 10^{-19}$$

$$= 8.76 \times 10^{-19} - 2 \times 10^{-19} = 6.76 \times 10^{-19}$$

$$= \frac{6.76 \times 10^{-19}}{1.6 \times 10^{-19}} \text{ eV}$$

$$\text{Work function, } \Phi_0 = 4.22 \text{ eV}$$

Work function,
$$\phi_0 = 4.22 \text{ eV}$$
(ii) $\lambda = 6328 \times 10^{-10} \text{ m}$ (1)

As,
$$KE_{max} = hv - \phi_0$$

Here, $hv = \frac{hc}{\lambda}$
 $= 3.14 \times 10^{-19} \text{ J}$

But,
$$\phi = 4.22 \text{ eV}$$

i.e. $hv < \phi$ [From Eq. (i)]
 $KE_{max} < 0$

which is not possible.

(1) Photoelectric effect does not take place.

53. Threshold frequency The minimum frequency below which there is no occurrence of photoelectric effect is called the cut-off frequency (1) or threshold frequency and denoted by v_0 .

Stopping potential Refer to Sol. 12 (1)

For wave theory of light Refer to Sol. 40 (ii) (1)

i.e.
$$K = qV \Rightarrow \frac{1}{2}mv^2 = qV$$

$$\Rightarrow \qquad p^2/2m = qV \Rightarrow p = \sqrt{2mqV}$$

avelength,

$$\lambda = h/p = h/\sqrt{2mqV}$$
(1)

4. de-Broglie hypothesis A moving object sometimes acts as a wave and sometimes as a particle or a wave is associated with the moving particle which control this particle in every respect. This wave associated with the moving particle is called matter wave or de-Broglie wave. Its wavelength is given by

$$\lambda = h/mv$$

where, h = Planck's constant, m = mass of object, v = velocity of the object.

5. de-Broglie wavelength, $\lambda = \frac{h}{n} = \frac{h}{\sqrt{2mK}}$

where,
$$K = KE$$

For given KE,
$$\lambda \propto \frac{1}{\sqrt{m}}$$

: Electron have smaller mass,

$$\therefore \qquad \qquad \lambda_e > \lambda_p \qquad \qquad [\because m_e < m_p]$$

For given kinetic energy, electrons have greater wavelength as it has smaller mass.

6. de-Broglie wavelength,
$$\lambda = \frac{h}{p} = \frac{h}{mv}$$

$$\frac{\lambda_1}{\lambda_2} = \frac{M_e \nu_e}{M_1 \nu_1} = 8.3 \times 10^{-4}$$

$$\therefore M_1 = \frac{M_e v_e}{8.3 \times 10^{-4} (3v_e)} \qquad (\because v_1 = 3v_e)$$

$$= \frac{9.1 \times 10^{-31}}{8.3 \times 10^{-4} \times 3} = 0.36 \times 10^{-27} \text{kg}.$$

Thus, the particle may be either proton or neutron.

2. de-Broglie wavelength, $\lambda = \frac{h}{\sqrt{2maV}}$ or

Explanations

1. de-Broglie wavelength

$$\lambda = \frac{h}{\sqrt{2mq}} \cdot \frac{1}{\sqrt{V}}$$
. The graph of λ versus $\frac{1}{\sqrt{V}}$ is a

straight line of slope $\frac{h}{\sqrt{2mq}}$. The slope of line B is

 $\lambda = h/p = h/\sqrt{2mKE} \implies \lambda^2 KE = constant$

small, so particle B has larger mass (charge is (1) same).

A charged particle having charge q and mass m then kinetic energy of the particle is equal to the work done on it by the electric field.

7. Kinetic energy,
$$K = \frac{p^2}{2m}$$

(1)

p = momentum

$$m = \text{mass}$$
 and $K = \text{kinetic energy}$

$$\Rightarrow \qquad p = \sqrt{2mK}$$

de-Broglie wavelength, $\lambda = \frac{h}{n}$

where,
$$p = \sqrt{2mK}$$

$$\Rightarrow \lambda = \frac{h}{\sqrt{2mK}} = \frac{h}{\sqrt{2mE}} \quad [:K = E]$$

(1)

8. Kinetic energy, K = eV

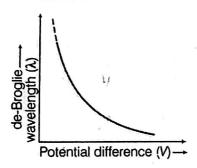

where, V = potential difference

$$\Rightarrow p = \sqrt{2mK} = \sqrt{2meV}$$

:. de-Broglie wavelength

$$\lambda = \frac{h}{p} = \frac{h}{\sqrt{2meV}} \implies \lambda \propto \frac{1}{\sqrt{V}}$$

 $\Rightarrow V \cdot \lambda^2 = \text{constant}$

9. Davisson-Germer experiment shows wave nature of electron.

The phenomenon of constructive interference was observed in Davisson-Germer experiment. (1)

10. Energy of photon, $E_p = \frac{hc}{\lambda}$

Energy of electron (moving particle), $E_e = \frac{1}{2} \frac{p^2}{m}$

de-Broglie wavelength associated with the moving particle is

Cole is
$$\lambda = h/p \text{ or } p = h/\lambda \tag{1}$$

$$E_e = \frac{1}{2} \frac{(h/\lambda)^2}{m} = \frac{1}{2} \frac{h^2}{\lambda^2 m}$$

$$\frac{E_p}{E_e} = \frac{hc/\lambda}{2 \lambda^2 m} = \frac{2m\lambda c}{h}$$
(1)

(1)

11. Given, $\lambda = 590 \text{ nm} = 590 \times 10^{-9} \text{ m}$

Mass of electron = 91×10^{-31} kg

Planck's constant, $h = 6.63 \times 10^{-34}$ J-s

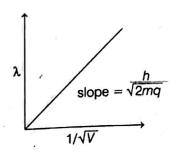

Using formula, $\lambda = \frac{h}{\sqrt{2mK}}$

Kinetic energy of electron,

$$K = \frac{h^2}{2\lambda^2 m_e} = \frac{(6.63 \times 10^{-34})^2}{2 \times (590 \times 10^{-9})^2 \times 91 \times 10^{-31}}$$
$$= 6.94 \times 10^{-25} \text{J}$$
 (2)

12. The de-Broglie wavelength is given by

$$\lambda = \frac{h}{\sqrt{2mqV}} \Rightarrow \lambda \propto \frac{1}{\sqrt{V}}$$

Thus, it gives a straight line graph.

$$\lambda \sqrt{V} = \frac{h}{\sqrt{2maV}} = \text{slope of graph}$$

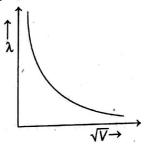

Knowing the mass of particle (m) and slope of graph, we can calculate charge (q) on a particle. (1)

(1)

13. (a) We know that, de-Broglie wavelength,

$$\lambda = \frac{h}{\sqrt{2mqV}} \text{ Å}$$

Hence, graph is as shown

(b) The de-Broglie wavelength, $\lambda = \frac{h}{\sqrt{2mK}}$

where, m = mass of particle

and K = kinetic energy of particle. As kinetic energy is same, for electron and proton and α -particle, so $\lambda \propto \frac{1}{\sqrt{m}}$.

Therefore, α-paritcle has shortest wavelength as its mass is more than electron and proton. (1)

14. We have, de-Broglie wavelength, $\lambda = \frac{h}{\sqrt{2mqV}}$

where, V is potential difference, q is charge of the particle and m is mass of the particle.

Given,
$$V_{\alpha} = V_{p} = V$$
 (say)

$$\frac{\lambda_{\alpha}}{\lambda_{p}} = \frac{\sqrt{2m_{p}q_{p}V}}{\sqrt{2m_{\alpha}q_{\alpha}V}} = \sqrt{\frac{m_{p}q_{p}}{m_{\alpha}q_{\alpha}}} = \sqrt{\frac{1}{4\times2}} = \frac{1}{2\sqrt{2}}$$

15. Given that λ is the wavelength of the photon. The de-Broglie wavelength of the electron is $\lambda = h/mV$ Kinetic energy of electron,

$$E_e = \frac{1}{2}mv^2 = \frac{1}{2}m\left(\frac{h}{m\lambda}\right)^2 = \frac{h^2}{2m\lambda^2}$$

We know that, energy of photon is $E_P = hc/\lambda$...(ii) on dividing Eq. (i) by Eq. (ii),

$$\frac{E_e}{E_p} = \frac{h^2}{2m\lambda^2} \times \frac{\lambda}{hc} \implies E_p = \frac{2\lambda mc}{h} E_e$$

16. (i) The de-Broglie wavelength of a particle is

$$\lambda = \frac{12.27}{\sqrt{V}} \text{\AA}$$

(here, V is the accelerating potential of the particle)

$$\therefore \quad \frac{\lambda_{\text{proton}} = \lambda_{\alpha}}{\sqrt{V_{\text{proton}}}} = \frac{12.27}{\sqrt{V_{\alpha}}} \implies \frac{V_{\text{proton}}}{V_{\alpha}} = 1$$
 (given)

(ii) The de-Broglie wavelength of α -particle is given by $\lambda = \frac{h}{mv}$

$$\lambda_{\text{proton}} = \frac{h}{m_{\text{proton}} \cdot v_{\text{proton}}} \text{ and } \lambda_{\alpha} = \frac{h}{m_{-}v}$$

: We know that, $m_{\alpha} = 4 m_{\text{proton}}$

$$\frac{\lambda_{\text{proton}} = \lambda_{\alpha}}{\frac{h}{m_{\text{proton}} \cdot \nu_{\text{proton}}} = \frac{h}{4m_{\text{proton}} \cdot \nu_{\alpha}}}$$
 (given)

$$\Rightarrow \frac{\nu_{\text{proton}}}{\nu_{\alpha}} = 4 \tag{1}$$

17. (i) de-Broglie wavelength is given by

$$\lambda = \frac{h}{\sqrt{2mV_0 q}} \implies \lambda \propto \frac{1}{\sqrt{m}}$$

[:: V_0 and q are same, because proton and deuteron have been accelerated by same potential and have same charge].

Since, mass of proton is less as compared to a deuteron. So, it will have higher value of de-Broglie wavelength associated with it. (1)

(ii) de-Broglie wavelength is given by

$$\lambda = h/p \implies p = h/\lambda$$
As, $\lambda_d < \lambda_p$
So, $p_d > p_p$ (1)

14. (i) de-Broglie wavelength is given by

$$\lambda = \frac{h}{\sqrt{2mV_0 q}} \Rightarrow \lambda \propto \frac{1}{\sqrt{mq}}$$

$$\frac{\lambda_d}{\lambda_u} = \frac{1/\sqrt{2me}}{1/\sqrt{4m2e}} = \frac{2}{1}$$

wavelength of deuteron is two times the wavelength of α -particle. (1)

(ii)
$$\frac{KE_d}{KE_{\alpha}} = \frac{V_0 e}{V_0 2e} = \frac{1}{2}$$

(1)

KE of deuteron is half of KE of α -particle.

19. From Einstein and photoelectric equation

$$K_{\text{max}} = hv - \phi_0$$

$$E = \phi_0 + K_{\text{max}}$$
[: E = hv]

According to the question, $\phi_0 = 0$

So,
$$E = K_{\text{max}}$$
$$E = p^2/2m$$

 $[::K_{\max}=p^2/2m]$

... (i)

...(i)

(1)

$$p=\sqrt{2mE}$$

de-Broglie wavelength is given by, $\lambda = h/p$ Substituting the value of p from λ Eq. (i), we get

$$\lambda = h/\sqrt{2mE} \quad (2)$$

F == -

20. Given, $v = 2.2 \times 10^8$ m/s de-Broglie wavelength is

$$\lambda = h/mV$$
Here, $m = 9.1 \times 10^{-31}$ kg

$$h = 6.63 \times 10^{-34} \text{ kg-m}^2\text{-s}$$

Substituting all values in Eq. (i), we get

$$\lambda = \frac{6.63 \times 10^{-34}}{9.1 \times 10^{-31} \times 2.2 \times 10^{8}}$$

$$\lambda = 3.31 \times 10^{-12} \text{ m}$$
(2)

21. Given, V = 100 V. Wavelength of accelerated electron beam from de-Broglie equation

$$\lambda = \frac{12.27}{\sqrt{V}} \text{ Å}$$

For
$$V = 100 \text{ V} \Rightarrow \lambda = 1.227 \text{ Å}$$

(1)

This wavelength belongs to the X-ray part of electromagnetic radiation.

$$\lambda = 1.02 \text{ Å}$$

This wavelength belongs to X-ray part of electromagnetic spectrum.

(S)
$$\lambda = 1.5 \text{ Å}$$
 and X-ray.

22. de-Broglie wavelength is given by

$$\lambda = h/\sqrt{2mK} = h/\sqrt{2mqV}$$

$$\Rightarrow \lambda \propto 1/\sqrt{mqV} \qquad (\because K = qV)$$

where, m = mass of charged particle,

q = charge, V = potential difference

 \therefore Ratio of de-Broglie wavelengths of proton and α -particle.

$$\frac{\lambda_p}{\lambda_\alpha} = \sqrt{\frac{m_\alpha q_\alpha V_\alpha}{m_p q_p V_p}} = \sqrt{\left(\frac{m_\alpha}{m_p}\right) \left(\frac{q_\alpha}{q_p}\right) \left(\frac{V_\alpha}{V_p}\right)} \tag{1}$$

Here, $\frac{m_{\alpha}}{m_{p}} = 4$, $\frac{q_{\alpha}}{q_{p}} = 2$

[(:α - particle is 4 times heavier than proton and it has double the charge than that of proton)]

$$\frac{V_{\alpha}}{V_{p}} = \frac{64}{128} = \frac{1}{2}$$

$$\therefore \frac{\lambda_p}{\lambda_\alpha} = \sqrt{4 \times 2 \times \frac{1}{2}} = 2 \text{ or } \lambda_p : \lambda_\alpha = 2:1$$

23. de-Broglie wavelength of accelerated charged particle is given by $\lambda = \frac{h}{\sqrt{2mqV}} \Rightarrow \lambda \propto \frac{1}{\sqrt{mqV}}$

Ratio of wavelengths of proton and α -particle.

$$\frac{\lambda_p}{\lambda_\alpha} = \sqrt{\left(\frac{m_\alpha}{m_p}\right) \left(\frac{q_\alpha}{q_{pl}}\right) \left(\frac{V_\alpha}{V_p}\right)} \tag{1}$$

Here, $\frac{m_{\alpha}}{m_{p}} = 4$, $\frac{q_{\alpha}}{q_{p}} = 2$, $\frac{V_{\alpha}}{V_{p}} = \frac{X}{512}$, $\frac{\lambda_{p}}{\lambda_{\alpha}} = 1$

$$\Rightarrow 1 = \sqrt{4 \times 2 \times \left(\frac{X}{512}\right)} = \frac{X}{64} \Rightarrow X = 64 \text{ V}$$
 (1)

24. : de-Broglie wavelength of accelerated charged particle is given by

$$\lambda = h/\sqrt{2mqV}$$

$$\Rightarrow \lambda\sqrt{V} = h/\sqrt{2mq} = \text{constant}$$

- (i) The slope of the line represents $h/\sqrt{2mq}$ where, h = Planck's gonstant, q = charge and m = mass of the charged particle. (1)
- (ii) : 1H² and 1H³ carry same charge (as they have same atomic number)

$$\therefore \qquad \lambda \sqrt{V} \propto \frac{1}{\sqrt{m}}$$

The lighter mass, i.e. ₁H² is represented by line of greater slope, i.e. A and similarly ₁H³ by line B.

25. Given, $V = 50 \text{ kV} = 50 \times 10^3 \text{ V}$

.. de-Broglie wavelength,

$$\lambda = \frac{12.27}{\sqrt{V}} \text{Å} = \frac{12.27}{\sqrt{50 \times 10^3}} \text{Å} = 0.0550 \text{Å}$$

Resolving power of a microscope, $R = \frac{2\mu \sin\theta}{\lambda}$

From the formula, it is clear that if other factors remains same, then resolving power is inversely proportional to wavelength of the radiation used. The wavelength of moving electron is very small as compared to that if yellow light; so it has greater resolving power than optical microscope.

26. (1) Refer to class notes

(ii) Energy of electron, E = eV

Momentum is given by

$$p = \sqrt{2 mE} = \sqrt{2 meV} \qquad \dots (i)$$

(11/2)

de-Broglie wavelength, $\lambda = \frac{h}{p}$...(ii)

From Eq. (i) substituting the value of p in Eq. (ii), we get

$$\lambda = \frac{h}{\sqrt{2 \, meV}}$$

27. (i) de-Broglie matter wave equation is given by

$$\lambda = \frac{h}{p} = \frac{h}{\sqrt{2mK}} \qquad (\because p = \sqrt{2mK})$$

where, m =mass of proton

K = kinetic energy of proton.

According to the question, kinetic energy of proton, $K = m_e c^2$

(Einstein's mass-energy relation

$$\Rightarrow \lambda = \frac{h}{\sqrt{2 m(m_e c^2)}}$$

$$\lambda = \frac{h}{\sqrt{2 c \sqrt{m m_e}}} = \frac{h}{\sqrt{2c \times (m_e) \sqrt{1836}}}$$

 $\lambda = \frac{6.63 \times 10^{-34}}{1.414 \times (3 \times 10^8) \times 9.1 \times 10^{-31} \times 42.8}$

 $\lambda = 4 \times 10^{-14} \text{ m}$

- (ii) This region of electromagnetic spectrum is X-ray.
- 28. (i) From de-Broglie matter wave equation,

$$\lambda = \frac{h}{mv} \implies m = \frac{h}{\lambda v}$$

Here, $\lambda = 0.135 \times 10^{-9} \text{ m} \Rightarrow v = 5 \times 10^6 \text{ m/s}$

$$m = \frac{6.63 \times 10^{-34}}{0.135 \times 10^{-9} \times 5 \times 10^{6}}$$
$$= 9.82 \times 10^{-31} \text{ kg}$$

(ii) This wavelength 0.135 nm falls in the region of X-ray of electromagnetic spectrum.

Given,
$$v_{\text{particle}} = 3 v_{\text{electron}}$$
 ...(i)

and $\lambda_{\text{particle}} = 1.813 \times 10^{-4} \lambda_{\text{electron}}$

(i) As,
$$\lambda = \frac{h}{mv}$$
 (de-Broglie equation)
$$\Rightarrow \frac{m_{\text{particle}}}{m_{\text{electron}}} = \frac{\lambda_{\text{electron}} \times v_{\text{electron}}}{\lambda_{\text{particle}} \times v_{\text{particle}}}$$

$$m_{\text{particle}} = 1839 \, m_{\text{electron}} \quad \text{[From Eq. (i)]}$$

$$m_{\text{particle}} = 1839 \times 9.1 \times 10^{-31}$$

$$= 1.673 \times 10^{-27} \text{ kg}$$
le is either a proton (2)

particle is either a proton or a neutron.

(ii) Now, $\lambda = h/\sqrt{2mK}$

As the kinetic energy is same for electron and proton, so $\lambda \propto \frac{1}{\sqrt{m}}$

As,
$$m_e < m_p \implies \lambda_p < \lambda_e$$
 (1)

30. (i) For electron and photon,

momentum
$$p = \frac{h}{\lambda} = \frac{6.63 \times 10^{-34}}{10^{-9}}$$

= 6.63×10⁻²⁵ m (1)

(ii)
$$E = \frac{hc}{\lambda} = \frac{(6.63 \times 10^{-34}) \times (3 \times 10^8)}{10^{-9} \times (1.6 \times 10^{-19})} = 1243 \,\text{eV}$$
 (1)

(iii) As,
$$E = \frac{p^2}{2m} = \frac{(6.63 \times 10^{-25})^2}{2 \times 9 \times 10^{-31} \times 1.6 \times 10^{-19}} = 1.52 \text{ eV}$$
 (1)
