# Chapter Five

# MAGNETISM AND MATTER

# **MCQ I**

- **5.1** A toroid of n turns, mean radius R and cross-sectional radius a carries current I. It is placed on a horizontal table taken as x-y plane. Its magnetic moment  $\mathbf{m}$ 
  - (a) is non-zero and points in the z-direction by symmetry.
  - (b) points along the axis of the tortoid ( $\mathbf{m} = m \mathbf{b}$ ).
  - (c) is zero, otherwise there would be a field falling as  $\frac{1}{r^3}$  at large distances outside the toroid.
  - (d) is pointing radially outwards.
- **5.2** The magnetic field of Earth can be modelled by that of a point dipole placed at the centre of the Earth. The dipole axis makes an angle of  $11.3^{\circ}$  with the axis of Earth. At Mumbai, declination is nearly zero. Then,
  - (a) the declination varies between  $11.3^{\circ}$  W to  $11.3^{\circ}$  E.
  - (b) the least declination is  $0^{\circ}$ .

- (c) the plane defined by dipole axis and Earth axis passes through Greenwich.
- (d) declination averaged over Earth must be always negative.
- **5.3** In a permanent magnet at room temperature
  - (a) magnetic moment of each molecule is zero.
  - (b) the individual molecules have non-zero magnetic moment which are all perfectly aligned.
  - (c) domains are partially aligned.
  - (d) domains are all perfectly aligned.
- 5.4 Consider the two idealized systems: (i) a parallel plate capacitor with large plates and small separation and (ii) a long solenoid of length L>>R, radius of cross-section. In (i)  $\bf E$  is ideally treated as a constant between plates and zero outside. In (ii) magnetic field is constant inside the solenoid and zero outside. These idealised assumptions, however, contradict fundamental laws as below:
  - (a) case (i) contradicts Gauss's law for electrostatic fields.
  - (b) case (ii) contradicts Gauss's law for magnetic fields.
  - (c) case (i) agrees with  $\iint \mathbf{E} . d\mathbf{l} = 0$ .
  - (d) case (ii) contradicts  $\iint \mathbf{H} \cdot d\mathbf{l} = I_{en}$
- **5.5** A paramagnetic sample shows a net magnetisation of 8 Am<sup>-1</sup> when placed in an external magnetic field of 0.6T at a temperature of 4K. When the same sample is placed in an external magnetic field of 0.2T at a temperature of 16K, the magnetisation will be
  - (a)  $\frac{32}{3}$  Am<sup>-1</sup>
  - (b)  $\frac{2}{3}$  Am<sup>-1</sup>
  - (c) 6 Am<sup>-1</sup>
  - (d) 2.4 Am<sup>-1</sup>.

# **MCQ II**

- ${f 5.6}$   ${f S}$  is the surface of a lump of magnetic material.
  - (a) Lines of  ${\bf B}$  are necessarily continuous across  ${\bf S}$ .
  - (b) Some lines of  ${\bf B}$  must be discontinuous across  ${\bf S}$ .
  - (c) Lines of  ${\bf H}$  are necessarily continuous across  ${\bf S}$ .
  - (d) Lines of  ${\bf H}$  cannot all be continuous across  ${\bf S}$ .

- **5.7** The primary origin(s) of magnetism lies in
  - (a) atomic currents.
  - (b) Pauli exclusion principle.
  - (c) polar nature of molecules.
  - (d) intrinsic spin of electron.
- **5.8** A long solenoid has 1000 turns per metre and carries a current of 1 A. It has a soft iron core of  $\mu_r = 1000$ . The core is heated beyond the Curie temperature,  $T_c$ .
  - (a) The  ${\bf H}$  field in the solenoid is (nearly) unchanged but the  ${\bf B}$  field decreases drastically.
  - (b) The  ${\bf H}$  and  ${\bf B}$  fields in the solenoid are nearly unchanged.
  - (c) The magnetisation in the core reverses direction.
  - (d) The magnetisation in the core diminishes by a factor of about  $10^8$ .
- **5.9** Essential difference between electrostatic shielding by a conducting shell and magnetostatic shielding is due to
  - (a) electrostatic field lines can end on charges and conductors have free charges.
  - (b) lines of  ${\bf B}$  can also end but conductors cannot end them.
  - (c) lines of  ${\bf B}$  cannot end on any material and perfect shielding is not possible.
  - (d) shells of high permeability materials can be used to divert lines of  ${\bf B}$  from the interior region.
- **5.10** Let the magnetic field on earth be modelled by that of a point magnetic dipole at the centre of earth. The angle of dip at a point on the geographical equator
  - (a) is always zero.
  - (b) can be zero at specific points.
  - (c) can be positive or negative.
  - (d) is bounded.

#### **VSA**

- **5.11** A proton has spin and magnetic moment just like an electron. Why then its effect is neglected in magnetism of materials?
- **5.12** A permanent magnet in the shape of a thin cylinder of length 10 cm has  $M = 10^6$  A/m. Calculate the magnetisation current  $I_{M}$ .
- **5.13** Explain quantitatively the order of magnitude difference between the diamagnetic susceptibility of  $N_2$  (~5 × 10<sup>-9</sup>) (at STP) and Cu (~10<sup>-5</sup>).

- **5.14** From molecular view point, discuss the temperature dependence of susceptibility for diamagnetism, paramagnetism and ferromagnetism.
- **5.15** A ball of superconducting material is dipped in liquid nitrogen and placed near a bar magnet. (i) In which direction will it move? (ii) What will be the direction of it's magnetic moment?

### SA

- **5.16** Verify the Gauss's law for magnetic field of a point dipole of dipole moment  $\mathbf{m}$  at the origin for the surface which is a sphere of radius R.
- **5.17** Three identical bar magnets are rivetted together at centre in the same plane as shown in Fig. 5.1. This system is placed at rest in a slowly varying magnetic field. It is found that the system of magnets does not show any motion. The north-south poles of one magnet is shown in the Fig. 5.1. Determine the poles of the remaining two.
- 5.18 Suppose we want to verify the analogy between electrostatic and magnetostatic by an explicit experiment. Consider the motion of (i) electric dipole p in an electrostatic field E and (ii) magnetic dipole m in a magnetic field B. Write down a set of conditions on E, B, p, m so that the two motions are verified to be identical. (Assume identical initial conditions.)
- **5.19** A bar magnet of magnetic moment m and moment of inertia I (about centre, perpendicular to length) is cut into two equal pieces, perpendicular to length. Let T be the period of oscillations of the original magnet about an axis through the mid point, perpendicular to length, in a magnetic field  $\mathbf{B}$ . What would be the similar period T' for each piece?
- **5.20** Use (i) the Ampere's law for  $\mathbf{H}$  and (ii) continuity of lines of  $\mathbf{B}$ , to conclude that inside a bar magnet, (a) lines of  $\mathbf{H}$  run from the N pole to S pole, while (b) lines of  $\mathbf{B}$  must run from the S pole to N pole.

#### LA

**5.21** Verify the Ampere's law for magnetic field of a point dipole of dipole moment  $\mathbf{m} = m\hat{\mathbf{k}}$ . Take C as the closed curve running clockwise along (i) the z-axis from z = a > 0 to z = R; (ii) along the quarter circle of radius R and centre at the origin, in the first quadrant of x-z plane; (iii) along the x-axis from x = R to x = a, and (iv) along the quarter circle of radius a and centre at the origin in the first quadrant of x-z plane.

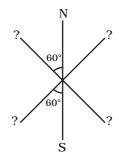

Fig. 5.1

- **5.22** What are the dimensions of  $\chi$ , the magnetic susceptibility? Consider an H-atom. Guess an expression for  $\chi$ , upto a constant by constructing a quantity of dimensions of  $\chi$ , out of parameters of the atom: e, m, v, R and  $\mu_0$ . Here, m is the electronic mass, v is electronic velocity, R is Bohr radius. Estimate the number so obtained and compare with the value of  $|\chi| \sim 10^{-5}$  for many solid materials.
- 5.23 Assume the dipole model for earth's magnetic field B which is given

by 
$$B_V$$
 = vertical component of magnetic field =  $\frac{\mu_0}{4\pi} \frac{2m\cos\theta}{r^3}$ 

$$B_{\rm H}$$
= Horizontal component of magnetic field =  $\frac{\mu_0}{4\pi} \frac{\sin\theta\,{\rm m}}{{
m r}^3}$ 

 $\theta$  = 90° – lattitude as measured from magnetic equator.

Find loci of points for which (i)  $|\mathbf{B}|$  is minimum; (ii) dip angle is zero; and (iii) dip angle is  $\pm$  45°.

- **5.24** Consider the plane S formed by the dipole axis and the axis of earth. Let P be point on the magnetic equator and in S. Let Q be the point of intersection of the geographical and magnetic equators. Obtain the declination and dip angles at P and Q.
- **5.25** There are two current carrying planar coils made each from identical wires of length L.  $C_1$  is circular (radius R) and  $C_2$  is square (side a). They are so constructed that they have same frequency of oscillation when they are placed in the same uniform  $\bf B$  and carry the same current. Find a in terms of  $\bf R$ .
