

# Motion in a Straight Line

## Motion

If an object changes its position with respect to its surroundings with time, then it is called in motion.

## Rest

If an object does not change its position with respect to its surroundings with time, then it is called at rest.

Rest and motion are relative states. It means an object which is at rest in one frame of reference can be in motion in another frame of reference at the same time.

**Point Object** An object can be considered as a point object, if the distance travelled by it is very large in comparison to its dimensions.

## Types of Motion

### 1. One Dimensional Motion

If only one out of three coordinates specifying the position of the object changes with respect to time, then the motion is called one dimensional motion or rectilinear motion.

For instance, motion of a block in a straight line, motion of a train along a straight track, a man walking on a level and narrow road and object falling under gravity etc.

### 2. Two Dimensional Motion

If only two out of three coordinates specifying the position of the object change with respect to time, then the motion is called two dimensional motion.

A circular motion is an instance of two dimensional motion.

### 3. Three Dimensional Motion

If all the three coordinates specifying the position of the object change with respect to time, then the motion is called three dimensional motion. A few instances of three dimension at motion are flying bird, a flying kite, the random motion of gas molecule etc.

### Frame of Reference

The most convenient system is a rectangular coordinate system of three mutually perpendicular axes as  $X$ ,  $Y$ , and  $Z$ . The point of intersection of these three axes is called origin ( $O$ ) and considered as the reference point. The  $x, y, z$ -coordinates describe the position of the object w.r.t the coordinate system. This coordinate system along with a clock constitutes a frame of reference.

### Distance or Path Length Covered

The length of the actual path covered by an object is called the distance.

It is a scalar quantity and it can never be zero or negative during the motion of an object. Its SI unit is metre.

### Displacement

The shortest distance between the initial and final positions of any object during motion is called displacement. The displacement of an object in a given time can be positive, zero or negative.

$$\text{Displacement, } \Delta x = x_2 - x_1$$

where,  $x_1$  and  $x_2$  are the initial and final positions of object, respectively.

It is a vector quantity. Its SI unit is metre.

### Speed

The time rate of change of position of the object in any direction is called speed of the object.

$$\text{Speed } (v) = \frac{\text{Distance travelled } (s)}{\text{Time taken } (t)}$$

Its SI unit is m/s.

It is a scalar quantity.

Its dimensional formula is  $[M^0LT^{-1}]$ .

## Uniform Speed

If an object covers equal distances in equal intervals of time, then its speed is called uniform speed.

## Non-uniform or Variable Speed

If an object covers unequal distances in equal intervals of time and *vice-versa* then its speed is called non-uniform or variable speed.

## Average Speed

The ratio of the total distance travelled by the object to the total time taken is called average speed of the object.

$$\text{Average speed} = \frac{\text{Total distance travelled}}{\text{Total time taken}}$$

If a particle travels distances  $s_1, s_2, s_3, \dots$  with speeds  $v_1, v_2, v_3, \dots$ , then

$$\text{Average speed} = \frac{s_1 + s_2 + s_3 + \dots}{\left( \frac{s_1}{v_1} + \frac{s_2}{v_2} + \frac{s_3}{v_3} + \dots \right)}$$

If particle travels equal distances ( $s_1 = s_2 = s$ ) with velocities  $v_1$  and  $v_2$ , then

$$\text{Average speed} = \frac{2v_1v_2}{(v_1 + v_2)}$$

If a particle travels with speeds  $v_1, v_2, v_3, \dots$  during time intervals  $t_1, t_2, t_3, \dots$ , then

$$\text{Average speed} = \frac{v_1t_1 + v_2t_2 + v_3t_3 + \dots}{t_1 + t_2 + t_3 + \dots}$$

If particle travels with speeds  $v_1$  and  $v_2$  for equal time intervals, i.e.  $t_1 = t_2 = t$ , then

$$\text{Average speed} = \frac{v_1 + v_2}{2}$$

When a body travels equal distance with speeds  $v_1$  and  $v_2$ , the average speed ( $v$ ) is the harmonic mean of two speeds, *i.e.*

$$\frac{2}{v} = \frac{1}{v_1} + \frac{1}{v_2}$$

## Instantaneous Speed

When an object is travelling with variable speed, then its speed at a given instant of time is called its instantaneous speed.

$$\text{Instantaneous speed} = \lim_{\Delta t \rightarrow 0} \frac{\Delta s}{\Delta t} = \frac{ds}{dt}$$

## Velocity

The time rate of change of displacement of an object in a particular direction is called its velocity.

$$\text{Velocity} = \frac{\text{Displacement}}{\text{Time taken}}$$

Its SI unit is m/s.

Its dimensional formula is  $[M^0LT^{-1}]$ .

It is a vector quantity, as it has both, the magnitude and direction.

The velocity of an object can be positive, zero or negative.

## Uniform Velocity

If an object undergoes equal displacements in equal intervals of time, then it is said to be moving with a uniform velocity.

## Non-uniform or Variable Velocity

If an object undergoes unequal displacements in equal intervals of time, then it is said to be moving with a non-uniform or variable velocity.

## Average Velocity

The ratio of the total displacement to the total time taken is called average velocity.

$$\text{Average velocity} = \frac{\text{Total displacement}}{\text{Total time taken}}$$

## Instantaneous Velocity

The velocity of a particle at any instant of time is known as instantaneous velocity.

$$\text{Instantaneous velocity} = \lim_{\Delta t \rightarrow 0} \frac{\Delta x}{\Delta t} = \frac{dx}{dt}$$

## Relative Velocity

Relative velocity of one object with respect to another object is the time rate of change of relative position of one object with respect to another object.

Relative velocity of object  $A$  with respect to object  $B$

$$\mathbf{V}_{AB} = \mathbf{V}_A - \mathbf{V}_B$$

If it is in one dimensional motion, we can treat vectors as scalars just by assigning the positive sign to one direction and negative to others.

When two objects are moving in the same direction, then

$$\mathbf{v}_{AB} = \mathbf{v}_A - \mathbf{v}_B$$

or  $v_{AB} = v_A - v_B$

When two objects are moving in opposite direction, then

$$\mathbf{v}_{AB} = \mathbf{v}_A + \mathbf{v}_B$$

or  $v_{AB} = v_A + v_B$

When two objects are moving at an angle  $\theta$ , then

$$v_{AB} = \sqrt{v_A^2 + v_B^2 - 2v_A v_B \cos \theta}$$

and  $\tan \beta = \frac{v_B \sin \theta}{v_A - v_B \cos \theta}$

## Acceleration

The rate of change of velocity with time is called acceleration.

$$\text{Acceleration } (a) = \frac{\text{Change in velocity } (\Delta v)}{\text{Time interval } (\Delta t)}$$

Its SI unit is  $\text{m/s}^2$ .

Its dimensional formula is  $[M^0 L T^{-2}]$ .

It is a vector quantity.

Acceleration can be positive, zero or negative. **Positive acceleration** means velocity increasing with time, **zero acceleration** means velocity is uniform while **negative acceleration** (retardation) means velocity is decreasing with time.

## Uniform Acceleration

If an object is moving with uniform acceleration, it means that the change in velocity is equal for equal interval of time.

## Non-uniform Acceleration

If an object is moving with non-uniform acceleration, it means that the change in velocity is unequal for equal interval of time.

## Average Acceleration

If a particle is accelerated for a time  $t_1$  with acceleration  $a_1$  and for a time  $t_2$  with acceleration  $a_2$ , then average acceleration

$$a_{\text{av}} = \frac{a_1 t_1 + a_2 t_2}{t_1 + t_2}$$

## Instantaneous Acceleration

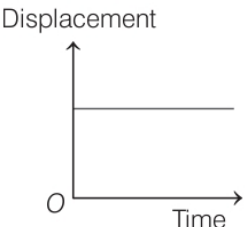

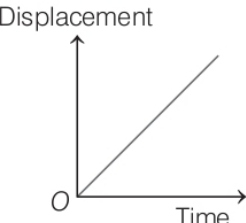

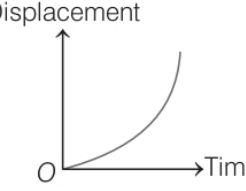

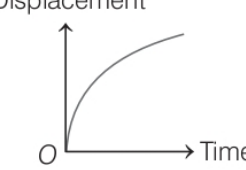

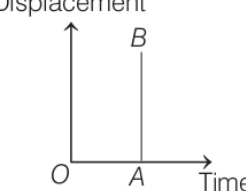

It is defined as the acceleration of object at any instant of time.

$$a_{\text{inst}} = \lim_{\Delta t \rightarrow 0} \frac{\Delta v}{\Delta t} = \frac{dv}{dt}$$

## Uniform Motion

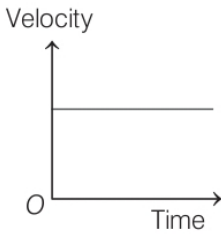

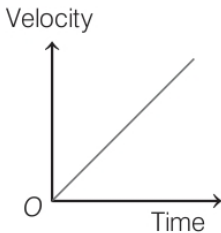

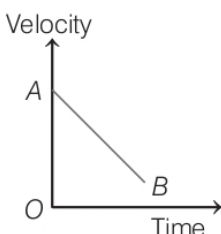

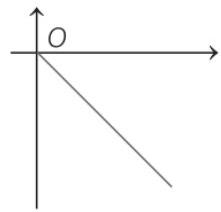

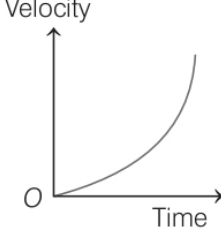

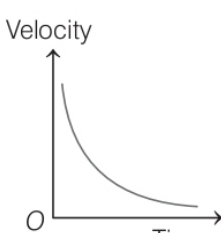

If an object is moving along the straight line covers equal distance in equal interval of time, it is said to be in uniform motion along a straight line.

### Different Graphs of Motion Displacement-Time Graph

| S. No. | Condition  | Graph  |
|--------|--|--|
| (a)    | For a stationary body  |  <p>A graph with Displacement on the vertical axis and Time on the horizontal axis. The origin is labeled 'O'. A horizontal line is drawn at a constant positive displacement value, indicating that the object's position does not change over time.</p>                                    |
| (b)    | Body moving with a constant velocity   |  <p>A graph with Displacement on the vertical axis and Time on the horizontal axis. The origin is labeled 'O'. A straight line starts from the origin and extends upwards and to the right at a constant slope, representing constant positive velocity.</p>                                |
| (c)    | Body moving with a constant acceleration   |  <p>A graph with Displacement on the vertical axis and Time on the horizontal axis. The origin is labeled 'O'. A parabolic curve starts from the origin and curves upwards, representing constant positive acceleration.</p>   |
| (d)    | Body moving with a constant retardation  |  <p>A graph with Displacement on the vertical axis and Time on the horizontal axis. The origin is labeled 'O'. A curve starts from the origin and curves upwards but with a decreasing slope, representing constant negative acceleration (retardation).</p>                               |
| (e)    | Body moving with infinite velocity. But such motion of a body is never possible. |  <p>A graph with Displacement on the vertical axis and Time on the horizontal axis. The origin is labeled 'O'. A vertical line is drawn at a constant time value 'A' on the horizontal axis, extending upwards to a point 'B' on the vertical axis. This represents infinite velocity.</p> |

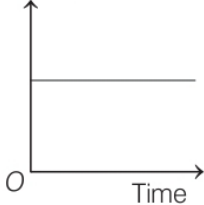

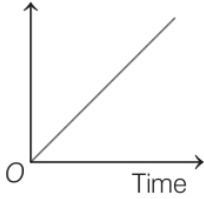

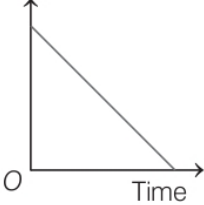

**Note** Slope of displacement-time graph gives average velocity.

## Velocity-Time Graph

| S. No. | Condition  | Graph   |
|--------|--|---|
| (a)    | Moving with a constant velocity  |  <p>A graph with Velocity on the vertical axis and Time on the horizontal axis. The origin is labeled 'O'. A horizontal line is drawn at a constant positive velocity value.</p>  |
| (b)    | Moving with a constant acceleration having zero initial velocity             |  <p>A graph with Velocity on the vertical axis and Time on the horizontal axis. The origin is labeled 'O'. A straight line starts at the origin and extends upwards with a constant positive slope.</p>   |
| (c)    | Body moving with a constant retardation and its initial velocity is not zero |  <p>A graph with Velocity on the vertical axis and Time on the horizontal axis. The origin is labeled 'O'. A straight line starts at a point 'A' on the positive velocity axis and extends downwards with a constant negative slope, ending at a point 'B' on the time axis.</p> |
| (d)    | Moving with a constant retardation with zero initial velocity                |  <p>A graph with Velocity on the vertical axis and Time on the horizontal axis. The origin is labeled 'O'. A straight line starts at the origin and extends downwards with a constant negative slope.</p>   |
| (e)    | Moving with increasing acceleration  |  <p>A graph with Velocity on the vertical axis and Time on the horizontal axis. The origin is labeled 'O'. A curve starts at the origin and curves upwards, becoming steeper as time increases.</p>   |
| (f)    | Moving with decreasing acceleration  |  <p>A graph with Velocity on the vertical axis and Time on the horizontal axis. The origin is labeled 'O'. A curve starts at a high positive velocity value and curves downwards, becoming flatter as time increases.</p>   |

**Note** Slope of velocity-time graph gives average acceleration.

## Acceleration-Time Graph

| S. No. | Condition   | Graph   |
|--------|---|---|
| (a)    | When object is moving with constant acceleration            | <div style="text-align: center;"> <p>Acceleration</p>  <p style="text-align: right;">Time</p> </div>  |
| (b)    | When object is moving with constant increasing acceleration | <div style="text-align: center;"> <p>Acceleration</p>  <p style="text-align: right;">Time</p> </div>  |
| (c)    | When object is moving with constant decreasing acceleration | <div style="text-align: center;"> <p>Acceleration</p>  <p style="text-align: right;">Time</p> </div> |

## Equations of Uniformly Accelerated Motion

If a body starts with velocity ( $u$ ) and after time  $t$  its velocity changes to  $v$ , if the uniform acceleration is  $a$  and the distance travelled in time  $t$  is  $s$ , then the following relations are obtained, which are called equations of uniformly accelerated motion.

$$(i) \quad v = u + at \qquad (ii) \quad s = ut + \frac{1}{2} at^2$$

$$(iii) \quad v^2 = u^2 + 2as$$

(iv) Distance travelled in  $n$ th second.

$$s_n = u + \frac{a}{2} (2n - 1)$$

If a body moves with uniform acceleration and velocity changes from  $u$  to  $v$  in a time interval, then the velocity at the mid-point of its path

$$= \frac{\sqrt{u^2 + v^2}}{2}$$

## Non-Uniformly Accelerated Motion

When acceleration of particle is not constant then motion is called non-uniformly accelerated motion.

For one dimensional motion,

$$v = \lim_{\Delta t \rightarrow 0} \frac{\Delta s}{\Delta t} = \frac{ds}{dt}$$
$$a = \lim_{\Delta t \rightarrow 0} \frac{\Delta v}{\Delta t} = \frac{dv}{dt} = v \cdot \frac{dv}{ds} = \frac{d^2s}{dt^2}$$

where,  $\Delta s$  is displacement in time  $\Delta t$ ,  $\Delta v$  is velocity in time  $\Delta t$  and  $a$  is instantaneous acceleration.

In component form,

$$\mathbf{a} = a_x \cdot \hat{\mathbf{i}} + a_y \cdot \hat{\mathbf{j}} + a_z \cdot \hat{\mathbf{k}}$$

where,  $a_x = \frac{dv_x}{dt}$ ,  $a_y = \frac{dv_y}{dt}$  and  $a_z = \frac{dv_z}{dt}$

## Motion Under Gravity

If an object is falling freely ( $u = 0$ ) under gravity, then equations of motion becomes

$$(i) v = u + gt \quad (ii) h = ut + \frac{1}{2}gt^2 \quad (iii) v^2 = u^2 + 2gh$$

**Note** If an object is thrown upward then  $g$  is replaced by  $-g$  in above three equations.

It thus follows that:

$$(i) \text{ Time taken to reach maximum height, } t_A = \frac{u}{g} = \sqrt{\frac{2h}{g}}$$

$$(ii) \text{ Maximum height reached by the body, } h_{\max} = \frac{u^2}{2g}$$

(iii) A ball is dropped from a building of height  $h$  and it reaches after  $t$  seconds on earth. From the same building if two ball are thrown (one upwards and other downwards) with the same velocity  $u$  and they reach the earth surface after  $t_1$  and  $t_2$  seconds respectively, then

$$t = \sqrt{t_1 t_2}$$

(iv) When a body is dropped freely from the top of the tower and another body is projected horizontally from the same point, both will reach the ground at the same time.
