

DCAM classes

The elements in which the last electron enters the outer most s - orbital are called s-block elements. The group I and II of periodic table belongs to the s-block.

# ALKALI METAL

#### **Physical State**

- (a) One electron in outermost sheel & General formula ns<sup>1</sup>.
- (b) Francium is radioactive element.
- (c) All are silvery white
- (d) Light soft, malleable and dutile metals with metallic lustre.
- (e) Alkali metal are paramagnetic, diamagnetic and colourless in form of ions.

#### **Atomic Size**

(a) Biggest in their repective period

(except noble gas element)

(b) Size increases from Li to Fr due to addition of an extra shell.

 $Li\!<\!Na\!<\!K\!<\!Rb\!<\!Cs\!<\!Fr$ 

#### Softness

- (a) Alkali metals are soft because of
  - (i) Large atomic size
  - (ii) BCC crystal structure (HCP in Li)
  - (iii) Loose packing (68 % packing efficiency)
  - (iv) Weak metallic bond
- (b) Cs is the softest metal in s-block

| Atomic size $\infty$ | 1                         | $\infty$ softness $\infty$ | 1                       |
|----------------------|---------------------------|----------------------------|-------------------------|
|                      | strength of metallic bond |                            | Melting & Boiling point |

# Melting point and boiling point

- (a) Weak interatomic bonds are due to their large atomic radil and presence of only one valence electron hence melting point and boiling point are low.
- (b) Decreasing order of melting point and biling point is Li > Na > K > Rb > Cs
- (c) With the increase in the size of metal atom, the repulsion of the non-bonding electrons increases and therefore melting point and boiling point decreases from Li to Cs.

#### Electro positive character or metallic character

Electropositive  $\propto 1$ /Ionisation Potentical

Due to their larger sixe electron can easily be removed to form M<sup>+</sup> ion. Electro positive property increases from Li to Cs.

#### Flame Test

Alkali metals and their salts gives characteristic colour to bunsen flame. The flame energy causes an excitation of the outer most electron which on dropping back to ground state emits absorbed energy as visible light

Ex.Li-Crimson redNa-Golden yellowK-VioletRb-Red violetCs-Blue

### Reaction with NH<sub>3</sub>

(a) 
$$2Li + NH_3 \rightarrow Li_2NH(Lithimide)$$

$$2Na + 2NH_3 \rightarrow 2NaNH_2 + H_2 \uparrow$$

(Sodamide)

(b) Solubility in liquid ammonia

(i) All the alkali metals dissolves in NH, (Liq.) and produces blue solution.

(ii) This blue solution conducts electricity and possesses strong reducting power, due to the presence of ammoniated electrons.

$$Na_{(s)} + (x+y) NH_3 \rightarrow [Na(NH_3)_x]^+ + [e(NH_3)_y]^-$$
  
ammoniated electron

(iii) This dilute solution is paramagnetic in nature.

# **Photo Electric Effect**

(a) Atomic size of K, Rb and Cs is quite large, so their ionisation potential is very low

(b) Due to very low ionisation potential their valuence shell electrons gets excited even by absorbing visible light. That's why Cs is used in photo cells.

# Standard oxidation potential

- (a) All the alkali metals have high +ve values of standard oxidation potential (tendency of relasing electrons in water or self ionic solutions)
- (b) So these are good reducing agent, having upper most position in the electro chemical series.
- (c) Li has highest standared oxidation potential (+3.05 eV) due to its high hydration energy. Such that is converts into. Li<sup>+</sup> ion by loosing one electron.

Order of standard oxidation potential of s-block element Li > K > Ba > Sr > Ca > Na > Mg > BeHydration energy  $\infty$  charge density on ion

#### Hydration energy (Heat of hydration)

- (a) Alkali metals salts are generally soluble in water due to hydration of cations by water molecules.
- (b) Smaller the cation, greater is the degree of its hydration.

 $K^{*}$ Na⁺ Rb⁺ (c)  $Li^{\dagger}$ Cs

- \* Degree of hydration decreasing
- \* Hydration energy decreasing
- \* Hydrated ion size decreasing
- \* Ionic conductance increasing

# **Reducing property**

- (a) Since alkali metals have high standard oxidation potential, so these are strongest reductants.
- (b) Reducing property increases down the group in gaseous or molten state

| Li <sup>+</sup> | < | $Na^+$ | < | $K^+$ | < | $Rb^+$ | < | $Cs^+$ |
|-----------------|---|--------|---|-------|---|--------|---|--------|
|                 |   |        |   |       |   |        |   |        |

#### **Reactioin with air**

(a) alkali metals gets turnish in air due to the formation of oxide at their surface hence they are kept in kerosence or paraffin oil.

(b) These elements reacts with moist air to form carbonates

 $4Na + O_2 \rightarrow 2Na_2O$ 

 $Na_2O + H_2O \rightarrow 2NaOH$ 

(moist)

$$2NaOh + CO_2 \rightarrow Na_2CO_3 + H_2O$$

(in air)

In dry air only Li gives nitride and oxide both while other elements gives only oxides.

#### **Reaction with oxygen**

Oxide ion  $\left[ O^{2^{-}} \right]$ 

Li forms only Li<sub>2</sub>O (Lithium oxide)

Peroxide  $\left[O_{2}\right]^{-2}$ 

Na reacts with  $O_2$  to form peroxide (Na<sub>2</sub>O<sub>2</sub>)

Super oxide  $\left[ O_{2}^{-} \right]$ 

K, Rb and Cs forms MO, type oxides (super oxides) in excess of O2. So super oxides are paramagnetic and coloured.

$$M \xrightarrow{O_2} M_2O \xrightarrow{O_2} M_2O_2 \xrightarrow{O_2} M_2O_2$$
  
Oxide perioxide Super  
(Li<sub>2</sub>O) (Na<sub>2</sub>O<sub>2</sub>) (KO<sub>2</sub>, RbO<sub>2</sub>, CsO<sub>2</sub>)

Their stability order is

Normaloxide > Peroxide > Superoxide

#### **Relaction with water**

(a) Alkali metals react vigorously with water forming hydroxisdes with the liberation of H<sub>2</sub>.

 $2M + 2H_2O \rightarrow 2MOH + H_2$ 

(b) Reactivity with water increases from Li to Cs.

 $Li \rightarrow$  least reactive towards water

 $Na \rightarrow reacts vigorously$ 

 $K \rightarrow$  reacts producing a flame

Rb, Cs  $\rightarrow$  reacts explosively

(c) These metals also reacts with alcohol gives alkoxide and H<sub>2</sub>.

 $2Li + 2C_2H_5OH \rightarrow 2C_2H_5O^-Li^+ + H_2$ 

(d) Monoxides gives strongly alkaline solution with water

 $M_2O + H_2O \rightarrow 2MOH$ 

#### Halides

(a) Alkali metals reacts directly with halogen to form MX

(M-alkalimetal, X-Halide ion)

(b) Ionic properties of MX increases from LiCl to CsCl

(c) LiCl is covalent in nature (due to polarisation of  $Cl^-$  ion by small Li<sup>+</sup> ion). hence it hydrolyses with water while reast are ionic so do not hydrolyse.

(d) K, Rb and Cs halides reacts with more halogens to gives polyhalides.

 $\mathsf{KI} + \mathsf{I}_2 \to \mathsf{KI}_3 \xrightarrow[\text{ionisation}]{} \mathsf{K}^{\scriptscriptstyle +} + \mathsf{I}_3^{\scriptscriptstyle -}$ 

 $CsBr + Br_2 \rightarrow CsBr_3 \rightarrow Cs^{\scriptscriptstyle +} + Br_3^{\scriptscriptstyle -}$ 

#### Carbonates

- (a) All the alkali metals forms M<sub>2</sub>CO<sub>3</sub> type carbonates.
- (b) Except  $Li_2CO_3$ , all the carbonates are stable towards heat

$$Li_2CO_3 \xrightarrow{\ } Li_2O + CO_2$$

(c) Thermal stability of carbonates  $\propto 1/\phi$  (Ionic potential)

Order of stability is

 $\mathbf{Cs}_{2}\mathbf{CO}_{3} > \mathbf{Rb}_{2}\mathbf{CO}_{3} > \mathbf{K}_{2}\mathbf{CO}_{3} > \mathbf{Na}_{2}\mathbf{CO}_{3} > \mathbf{Li}_{2}\mathbf{CO}_{3}$ 

#### Nitrates

(a) Alkali metals forms MNO<sub>3</sub> type nitrates (M - alkali metal)

(b) Stability increases from LiNO<sub>3</sub> to CsNO<sub>3</sub>. LiNO<sub>3</sub> decompoes into Lithium oxide & NO<sub>2</sub> on heating

$$4\text{LiNO}_3 \xrightarrow{a} 2\text{Li}_2\text{O} + 4\text{NO}_2 + \text{O}_2$$

(c) Other nitrates, on heating to give nitrite and oxygen.

$$\mathsf{MNO}_3 \xrightarrow{\ } 2\mathsf{MNO}_2 + \mathsf{O}_2$$

#### Nitrides

Only Li reacts directly with N, to form nitride which gives NH, on reacting with water.

$$6Li + M_2 \rightarrow 12Li_3N$$
  
$$Li_3N + 3H_2O \rightarrow 3LiOH + NH_3 \uparrow$$

# Formation of Amalgam

(a) Alkali metals gives amalgam with Hg.

(b) These metals reacts with other metals to give mixed metals (alloys)

#### Sulphates

(a) Alkali metals forms  $M_2SO_4$  type sulphates

(b) All alkali metal sulphates are ionic. Ionic properties increases from Li to Cs.

$$i_2SO_4 < Na_2SO_4 < K_2SO_4 < Rb_2SO_4 < Cs_2SO_4$$

(c)  $Li_2SO_4$  Least soluble in water.

(d) These sulphates on burning with C forms sulphides

 $M_2SO_4 + 4C \rightarrow M_2S + 4CO$ 

(e) Except lithium, sulphates of IA group reacrts with

sulphates of trivalent metla like Fe<sup>+3</sup>, Cr<sup>+3</sup>, Al<sup>+3</sup> etc. gices double salts called alum.

$$M_{2} \overset{1}{SO}_{4} . \overset{1}{M_{2}} (SO_{4})_{3} . 24H_{2}O$$

#### **Reaction with acids**

Reacts vigorously with acids

 $2M + H_2SO_4 \rightarrow M_2SO_4 + H_2$ 

- **Ex.** The first three elements of Group 1 have tghe following atomic structures
  - (a) Lithium : 3P, 4n ; 2, 1 electrons
  - (b) Sodium : 11p, 12n; 2, 8, 1 electrons
  - (c) Potassium : 19p, 20n; 2, 8, 8, 1 electrons

Which of the following features causes them to have similar properties

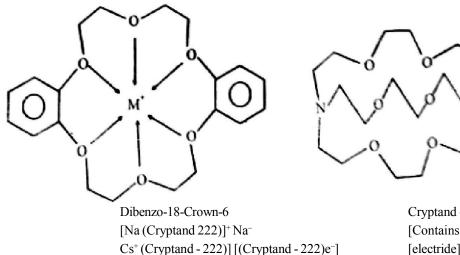

- (A) The same number of protons
- (B) More protons than electrons
- (C) Two electrons in the first shell
- (D) One electron in the outermost shell

#### Ans (D)

- **Sol.** One electron in the outermost shell.
- Ex. Considering greater polarization in LiCl compared to theat in NaCl, which of the following statements you would expect to be wrong ?
  - (A) LiCl has lower melting point than that of NaCl
  - (B) LiCl dissolves more in organic solvents
  - (C) LiCl will ionize in water more than NaCl
  - (D) Fused LiCl would be less conducting that fused NaCl.
- Ans (C)
- **Sol.** According to fajan's rules, heigher the polarization, higher is the covalent caharacter. Thus LiCl is covalent while NaCl is ionic. As a result LiCl will not ionize in water more than NaCl.
- **Ex.** Sodium ordinarily does not show an oxidation state of +2, because of its
  - (A) High firs :ionization potential
  - (B) High second ionization potential
  - (C) Large ionic radius
  - (D) High electronegativity
- Ans. **(B)**
- **Ex.** Mark the false statement
  - (A) The electropositive character of alkali metals decreases with increase in atomic number
  - (B) Lithium is hard metal and cannot be cut with a knife
  - (C) Alkali metals are strong reducing agents
  - (D) Electronegativities of all alkali metals lie between 1.0 to 0.7.

Ans (A)

# **Crown Ethers and Cryptands**

Cryptand - 222 [Contains Na<sup>-</sup> (sodide ion)] [electride]

# **Diagonal Relationship**

Lithium shows diagnal relationship with magnesium since they have almost the same polarizing power, i.e., charge/ size ratio  $\sim$ 

Lithium resembles magnesium in the following respects :

(i) Atomic size of Li (1.34 A) and Mg (1.36 A) are not much different.

(ii) ionic size of  $Li^+$  (0.60 A) and  $Mg^{2+}$  (0.65 A) are almost identical

(iii) polarizing power (i.e., ionic charge to ionic radius ratio) of Li<sup>+</sup> and Mg<sup>2+</sup> are about the same

- (iv) electronegativities of Li(1.00) and Mg(1.20) are not much different
- (v) both Li and Mg and hard metals

(vi) both decompose water only on heating

(vii) both combine with oxygen to form monoxides,

(viii) both LiOH and Mg(OH), are weak bases

(ix) both LiCl and  $MgCl_2$  are predominantly covalent and hence are soluble in organic solvents, such as alcohol and pyridine

(x) both Li and Mg combine with nitrogen to form their respectively nitrides, Li<sub>3</sub>N and Mg<sub>3</sub>N<sub>2</sub>.

(xi) carbonates, cluorids, oxalates and phospheates of both Li and Mg are sparingly soluble in H<sub>2</sub>O.

(xii) the hydroxides and carbonates of both Li and Mg decompose on heating forming their respective oxides.

(xiii) bothe lithium and magnesium nitates on heating evolve NO<sub>2</sub> and O<sub>2</sub> leaving behind their oxides.

# Ore of alkali metals

Since alkali metals are highly reactive metals, they do not occur in free state in nature sodium and potassium are quite abundant in the earth's crust with 7th and 8th position in the order of abundance of elements

| <b>(A)</b> | <b>Ores of Lithium</b><br>(i) Spodumene, LiAlSi <sub>2</sub> O <sub>6</sub>  | (ii) Lepidolite, (Li) <sub>2</sub> Al <sub>2</sub> (Si                 | O <sub>3</sub> ) <sub>3</sub> . (FOH) <sub>2</sub> |
|------------|--|--|--|
| <b>(B)</b> | Ores of Sodium<br>(i) Common salt or rock salt, NaCl<br>(iii) Albite (Soda Feldspar), NaAlSi <sub>3</sub> O <sub>8</sub> | (ii) Chile salt patre, NaN(<br>(iv) Glauber's salt, Na <sub>2</sub> SC |  |
| <b>(C)</b> | <b>Ores of Potassium</b><br>(i) Camallite, KCl. MgCl <sub>2</sub> . 6H <sub>2</sub> O                                    | (ii) Feldspar, KAlSi <sub>3</sub> O <sub>8</sub>                       | (iii) Sylvine, KCl                                 |

# Extraction of alkali metals

| (i)         | <ul> <li>Lithium: Extraction of lithium involves two steps</li> <li>Preparation of Licl form the ore 2. Electrolysis of LiCl</li> </ul>  |   |  |  |  |  |  |
|-------------|--|---|--|--|--|--|--|
|             | *  | red in 55% LiCl and 45% KCl. The electrolyte is maintained in molten state by                                 |  |  |  |  |  |
| <b>(ii)</b> | Sodium   |   |  |  |  |  |  |
|             | Down's Process   |   |  |  |  |  |  |
|             | In this method, Sodium is obtained by the electrolysis of a mixture of sodium chloride (40%) and calcium chloride (60%) in fused state. The function of calcium chloride is to lower the operating temperature from 1080 K (m.pt. of NaCl) to about 850 K. |   |  |  |  |  |  |
|             | The following reactions take place:  |   |  |  |  |  |  |
|             |  | $NaCl \rightarrow Na^+ + Cl^-$ (Ionization)   |  |  |  |  |  |
|             | At cathode :   | $Na^+ + e^- \rightarrow Na$   |  |  |  |  |  |
|             | At anode :   | $Cl^- \rightarrow Cl + e^-$   |  |  |  |  |  |
|             | The dodium metal obtained by this  | $Cl + Cl \rightarrow Cl_2 \uparrow$<br>nethod is about 99% pure. Chlorine is the b y - product in this press. |  |  |  |  |  |
|             |  |   |  |  |  |  |  |
| (iii)       | Potassium : potassium is obtained b  | y electrolysis of fused potassium hydroxide (KOH)   |  |  |  |  |  |
|             |  | $\mathrm{KOH} \to \mathrm{K}^+ + \mathrm{OH}^-$   |  |  |  |  |  |
|             | At cathode :<br>At anode :   | $K^+ + e^- \rightarrow K$<br>40H <sup>-</sup> $\rightarrow O_2 + 2H_2O + 4e^-$                                |  |  |  |  |  |
|             | At anode .   | $40H \rightarrow 0_2 + 2H_2O + 4e$  |  |  |  |  |  |
| Ex.         |  | ammonia to give blue coloured solution. The blue colour is believed to be due to                              |  |  |  |  |  |
|             | (A) Ammoniated cations   | (B) Ammoniated anions   |  |  |  |  |  |
|             | (C) Ammoniated electrons   | (D) Ammoniated cations and ammoniated electrons   |  |  |  |  |  |
| Ans.        | (C)  |   |  |  |  |  |  |
| Sol.        | Ammoniated electrons, i.e.   |   |  |  |  |  |  |
|             | $Na(s)+(x+y)NH_3 \rightarrow Na^+(NH_3)_{Blue colour}$   | $_{x}+e^{-}(NH_{3})_{y}$  |  |  |  |  |  |
| Ex.         | Choose the compound which does   | not poossies a peroxide group   |  |  |  |  |  |
|             | (A) $Na_2O_2$ (B) CrO  | $_{5}$ (C) Fe <sub>2</sub> O <sub>3</sub> (D) BaO <sub>2</sub>  |  |  |  |  |  |
| Ans.        | (C)  |   |  |  |  |  |  |
|             |  |   |  |  |  |  |  |
| Ex.         | $Na_2O_2$ is $Na^+O - O^-Na^+$ ; $CrO_5$ is  |   |  |  |  |  |  |
|             |  |   |  |  |  |  |  |
|             | BaO <sub>2</sub> is Ba <sup>2+</sup> ( $^{-}O - O^{-}$ ) while   | $Fe_2O_3$ consists of only $Fe^{3+}$ and $O^{2-}$ ions. Thus $Fe_2O_3$ does not contain a                     |  |  |  |  |  |
|             | peroxide $(^{-}O - O^{-})$ linkage   | 23  |  |  |  |  |  |
| -           | × ,  |   |  |  |  |  |  |
| Ex.         |  | eous solution of an oxide produces $CO_2$ . This reaction indicates that                                      |  |  |  |  |  |
|             | (A) Oxide is basic   | (B) Oxide is amphoteric   |  |  |  |  |  |
|             | (C) Oxide is that of a metal   | (D) Oxide is that of a non-metal  |  |  |  |  |  |

Ans (D)

- Ex. Alkali metal when exposed to air tarnish quickly due to the
  - (A) Formation of their hydroxides
- (B) Formation of their carbonates
- (C) Formation of their oxides

Ans (D)

# **COMPOUNDS OF ALKALI METALS**

(D) All the above

# 1. SODIUM (NA), NATRIUM

- (a) Extraction : Down's Process
  - By Electrolysis of fused NaCl + CaCl<sub>2</sub> + NaF At cathode (Iron Vessel) : Na<sup>+</sup> +e<sup>-</sup>  $\longrightarrow$  Na(s) At Anode (Graphite) : 2Cl<sup>-</sup>  $\longrightarrow$  Cl<sub>2</sub> + 2e<sup>-</sup>
- (i)  $(CaCl_2 + NaF)$  is used to lower Melting point (800°C) of NaCl to about 600°C.
- (ii) Aqueous sodium chloride cannot be used for preparing sodium by electrolysis. Because instead of metallic sodium, hydrogen gas will be liberated at cathode.

#### (b) **Properties**

- (i) It is a crystalline soft metal.
- (ii) Highly reactive, so kept in kerosene.
- (iii) Na dissolves in liquid NH<sub>3</sub> to give blue solution.

(c) Uses

- (i) In the preparation of sodium amalgam (used as reducing agent)
- (ii) In sodium vapour lamp, which emits monochromatic yellow light.
- (iii) As heat transfer medium in nuclear reactors.

#### 2. SODIUM CHLORIDE NaCl

- (a) Occurrence : Sea water is the main source and also found in salt lakes.
- (b) **Preparation**
- (i) Sea water NaCl(2.7 2.9%)  $\xrightarrow{\text{Evaporation}}$  crude NaCl
- (ii) It contains impurities  $-Na_2SO_4$ , MgCl<sub>2</sub>, CaCl<sub>2</sub> etc.
- (iii) Insoluble impurities removed by filtration.
- (iv) Filtrate  $\xrightarrow{HCl \text{ gas passed}}$  Pure NaCl precipitation (Common ion effect) HCl  $\iff$  H<sup>+</sup> + Cl<sup>-</sup> NaCl  $\iff$  Na<sup>+</sup> + Cl<sup>-</sup> Ionic product of [Na<sup>+</sup>] [Cl<sup>-</sup>] > solubility product of NaCl hence it precipitates out.
- (v) MgCl, and CaCl, are more soluble in water so left in solution.

#### (c) **Properties**

- (i) Table salt is slightly hygroscopic due to the presence of magnesium and calcium chlorides in small amounts.
- (ii) Reaction with  $AgNO_3$ NaCl +  $AgNO_3 \rightarrow NaNO_3$  + AgCl(white ppt.)Reaction with  $K_2Cr_2O_7$  + conc.  $H_2SO_4$

(iii) 
$$4\text{NaCl} + \text{K}_2\text{Cr}_2\text{O}_7 + 5\text{H}_2\text{SO}_4 \xrightarrow{\Delta} 4\text{NaHSO}_4 + \text{K}_2\text{SO}_4 + 2\text{CrO}_2\text{Cl}_2 + 3\text{H}_2\text{O}$$

(orange red)

- (d) Uses
- (i) As a preservative for pickles, meat and fish.
- (ii) For making freezing mixture with Ice.

#### 3. SODIUM HYDROXIDE (NaOH), CAUSTIC SODA

- (a) Manufacture : By electrolysis of NaCl.
- (b) Nelson Cell or Diaphragm Cell : The following reactions takes place –

 $NaC(aq.) \iff Na^{+} + CI^{-}$  $H_2O \iff H^{+} + CH^{-}$ 

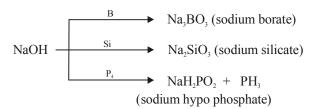

At cathode (Perforated steel):  $2H^+ + 2e^- \rightarrow H_2(g)$  At anode (Carbon):  $2Cl^-(aq.) \rightarrow Cl_2(g) + 2e^-$ 

Electrolite (Brine) NaCl  $\iff$  Na<sup>+</sup> + Cl<sup>-</sup> On electrolysis – At Cathode (Hg) Na<sup>+</sup> + e<sup>-</sup>  $\rightarrow$  Na. and Na + Hg  $\rightarrow$  Na.Hg (amalgum) At anode (Graphite) 2Cl<sup>-</sup>  $\rightarrow$  Cl<sub>2</sub>(g) + 2e<sup>-</sup> and 2Na.Hg + 2H<sub>2</sub>O  $\rightarrow$  2NaOH + H<sub>2</sub> + 2Hg

- (d) **Properties**
- (i) It is deliquescent white crystalline solid.
- (ii) It absorbs  $CO_2$  from air forming  $Na_2CO_3$ .
- (iii) NaOH is strong base

NaOH 
$$\xrightarrow{\text{SiO}_2}$$
 Na<sub>2</sub>SiO<sub>3</sub> + H<sub>2</sub>O  
Al<sub>2</sub>O<sub>3</sub>  $\rightarrow$  2NaAlO<sub>2</sub> + H<sub>2</sub>O

(iv) **Reaction with non metals :** no reaction with H<sub>2</sub>, N<sub>2</sub> and C

#### (v) Reaction with halogens

 $X_{2} \xrightarrow[NaOH (cold/dil)]{NaOH (cold/dil)} NaX + NaOX (Sodium hypo halite)$  $X_{2} \xrightarrow[NaOH (Hot/conc.)]{NaOH (Hot/conc.)} NaX + NaOX_{3} (Sodium Halate)$  $(X_{2} = Cl_{2}, Br_{2}, I_{2})$ 

(vi) **Reaction with Metal** Alkali metal No reaction  $2AI + 2H_2O$  > 2NaAlO<sub>2</sub> (Sodium meta aluminate) +  $H_2$  $\xrightarrow{Be} Na_2BeO_2$  (Sodium Berrylate) + H, NaOH —  $Z_n \rightarrow Na_2ZnO_2$  (Sodium zincate) + H,  $Sn \rightarrow Na_2SnO_2$  (Sodium stannite) + H,  $Pb \rightarrow Na_{Pb}O_{2}$  (Sodium plumbite) + H<sub>2</sub> (vii) Reaction with ZnCl, or ZnSO<sub>4</sub>  $ZnCl_2 + 2NaOH \longrightarrow Zn(OH)_2 + 2NaCl$  $Zn(OH)_2 + 2NaOH \longrightarrow Na_2[Zn(OH)_4]$ (Soluble complex) The hydroxides of aluminium, zinc, lead and tin, however, dissolve in excess of sodium hydroxide giving clear (viii) solution which can also be obtained when these metals are acted upon by the concentrated solution of sodium hydroxide.  $Zn(OH)_2 + 2OH^- \longrightarrow [Zn(OH)_4]^{2-}$ Zincate ion  $Al(OH)_3 + 3OH \longrightarrow [Al(OH)_6]^{3-}$ Aluminate ion Uses (e) In the manufacture of soap, rayon, dyes, paper and drugs. (i) In petroleum refining. (ii) 4. SODIUM BICARBONATE OR BAKING SODA (NaHCO,) Preparation: Solvay process (Commercial Scale) **(a)**  $CaCO_3 \longrightarrow CaO + CO_2$  (In brine saturated with NH<sub>3</sub>, CO<sub>2</sub> is passed)  $NH_3 + H_2O + CO_2 \longrightarrow NH_4HCO_3$  $NaCl + NH_4HCO_3 \longrightarrow NH_4Cl + NaHCO_3$  $2NH_4Cl + CaO \longrightarrow CaCl_2 + 2NH_3 + H_2O$  (Bye-products) **(b) Properties**  $NaHCO_3 + H_2O \implies NaOH + H_2CO_3$ **Hydrolysis**  $2NaHCO_3 \longrightarrow Na_2CO_3 + H_2O + CO_2\uparrow$ Effect of heat (temp. > 100°C) (Process occurs during preparation of cake)  $NaHCO_3 + HCl \longrightarrow NaCl + H_2O + CO_2\uparrow$ **Reaction with acids** - gives CO<sub>2</sub>  $NaHCO_3 + NaOH \longrightarrow Na_2CO_3 + H_2O$ **Reaction with base (c)** Uses (i) In the preparation of baking powder. (ii) In the preparation of effervescent drinks. In the fire extinguishers. As antacid medicine (removing acidity) (iii) (iv)

5. SODIUM CARBONATE OR WASHING SODA (Na, CO, 10H, O) Occurrence : Na<sub>2</sub>CO<sub>3</sub>–Soda ash. **(a)** Manufacture : By solvay process **(b)** Concentrated aqueous solution of NaCl is saturated with NH<sub>2</sub>. (i) (ii) Current of CO<sub>2</sub> passed through the solution. NaHCO, precipitated -(iii)  $NH_3 + CO_2 + H_2O \longrightarrow NH_4HCO_3 \iff NH_4^+ + HCO_3^ NaCl \implies Na^+ + Cl^ [Na^+] \times [HCO_3^-] > K_{sp} \text{ of } NaHCO_3 \text{ (so ppt. forms)}$  $2NaHCO_3 \longrightarrow Na_2CO_3 + H_2O + CO_2$ Potassium bicarbonate (KHCO<sub>3</sub>) cannot be prepared by solvay process as it is soluble in water. (iv) **Leblanc Process** (c)  $NaCl + H_2SO_4(conc.) \longrightarrow NaHSO_3 + HCl$  $NaCl + NaHSO_4 \xrightarrow{Strongly} Na_2SO_4 + HCl$ (Salt Cake)  $Na_{SO_4} + 4C \longrightarrow Na_{S}S + 4CO^{\uparrow}$  $Na_2S + CaCO_3 \longrightarrow Na_2CO_3 + CaS$ 

(d) **Properties** 

(i) **Efflorescence** 

Na<sub>2</sub>CO<sub>3</sub>.

Na<sub>2</sub>CO<sub>3</sub>.10H<sub>2</sub>O when exposed to air it gives out nine out of ten H<sub>2</sub>O molecules.

$$10H_2O \longrightarrow Na_2CO_3H_2O + 9H_2O$$
  
(Monohydrate)

This process is called efflorescence. Hence washing soda losses weight on exposure to air.

(ii) **Hydrolysis** : Aqueous solution of Na<sub>2</sub>CO<sub>3</sub> is alkaline in nature due to anionic hydrolysis.

$$Na_2CO_3 \longrightarrow 2Na^+ + CO_3^{-2}$$
 and  $CO_3^{-2} + H_2O \Longrightarrow H_2CO_3 + 2OH^-$   
(Carbonic acid)

(e) Uses

(i) For making fusion mixture 
$$(Na_2CO_3 + K_2CO_3)$$

- (ii) In the manufacture of glass, caustic soda, soap powders etc.
- (iii) In laundries and softening of water.

#### 6. SODIUM PEROXIDE Na,O,

(a) Sodium peroxide is manufacured by heating sodium metal on aluminium trays in air (free from  $CO_2$ )

 $2Na + O_2(air) \longrightarrow Na_2O_2$ 

- (i) When pure it is colourless, and the faint yellow colour of the usual product arises from the presence of a small amount of NaO<sub>2</sub>.
- (ii) When it is exposed, it comes in contact with moist air and turns white due to formation of NaOH and Na<sub>2</sub>CO<sub>3</sub>. Thus

$$Na_2O_2 + 2H_2O \longrightarrow 2NaOH + H_2O_2$$
 and  $2NaOH + CO_2 \longrightarrow Na_2CO_3 + H_2O$ 

(iii) Sodium peroxide is a powerful oxidizing agent and oxidizes chromium (III) hydroxide to sodium chromate, manganese (II) to sodium manganate and sulphides to sulphates.

$$2Cr(OH)_3 + 3O_2^{-2} \longrightarrow CrO_4^{-2} + 2OH^- + 2H_2O$$

(b) Uses

- (i) Sodium peroxide is widely used as an oxidizing agent yielding in inorganic chemisty; its reaction with organic compounds are dangerously violent.
- (ii) Sodium readily combines with carbon dioxide, sodium carbonate and oxygen, it may be used for the purification of air in confined spaces such as submarines.
- (iii) It is also used as a bleaching agent because of its oxidizing property.
- (iv) Sodium peroxide is used in the manufacture of dyes, and many other chemicals such as benzoyl peroxide, sodium perborate etc.

#### 7. SODIUM MONOXIDE

#### Sodium Monoxide (Na,O)

**Preparation** : It is obtained by burning sodium at 180°C in a limited supply of air or oxygen and distilling off the excess of Na in vacuum or by heating Na<sub>2</sub>O<sub>2</sub> (sodium peroxide), sodium nitrate (NaNO<sub>3</sub>) with sodium.

$$2Na + \frac{1}{2}O_2 \rightarrow Na_2O$$

$$Na_2O_2 + 2Na \rightarrow 2Na_2O$$

$$2NaNO_3 + 10Na \rightarrow 6Na_2O + N_2$$

#### **Properties**

- (i) It is a white amorphous substance.
- (ii) It reacts with water violently forming NaOH.

$$Na_2O + H_2O \rightarrow 2NaOH$$

(iii) On heating above 400°C, it disproportionate to give peroxide and metallic sodium.

$$2Na_2O \xrightarrow{400^{\circ}C} Na_2O_2 + 2Na_2O_2$$

(iv) It reacts with liquid ammonia forming sodamide and NaOH.

$$Na_2O + NH_2 \rightarrow NaOH + NaNH_2$$

#### 8. SODIUM CHLORIDE (NaCl)

#### Preparation

It is also called common salt occurs abundantly in nature as rock salt or halite. The most abundant source is seawater where sodium chloride occurs to the extent of 2.6 - 2.9 percent. The sea water is exposed to the sun and air in large shallow pits. The gradual evaporation of water lead to the crystallization of the salt. The purification is done by dissolving the salt in minimum volume of water and filtering if necessary, to remove insoluble impurities. The solution in the saturated with a current of dry hydrogen chloride whereby crystals of pure sodium chloride separate out.

#### **Properties**

(i) NaCl is a colourless crystaline salt, almost insoluble in alcohol and highly soluble in water.

(ii) It gives rise to HCl when heated with conc.  $H_2SO_4$  and  $Cl_2$  with  $MnO_2$  plus  $H_2SO_4$ 

 $NaCl + H_2SO_4 \rightarrow NaHSO_4 + HCl \uparrow$ 

 $NaHSO_4 + NaCl \rightarrow Na_2SO_4 + HCl \uparrow$ 

 $2\text{NaCl} + \text{MnO}_2 + 2\text{H}_2\text{SO}_4 \rightarrow \text{MnSO}_4 + \text{Na}_2\text{SO}_4 + 2\text{H}_2\text{O} + \text{Cl}_2 \uparrow$ 

**Ex.** Give reason for decreasing order of conductivity of following

$$Cs^{\scriptscriptstyle +} > Rb^{\scriptscriptstyle +} > K^{\scriptscriptstyle +} > Na^{\scriptscriptstyle +} > Li^{\scriptscriptstyle +}$$

**Sol.** Ions are hydrate in solution. Since Li is very small it is heavily hydrate. This make the radius of the dydrated ions large and hence it moves only slowly (although Li<sup>+</sup> is very small) and the radius of hydrated Cs<sup>+</sup> ion is smaller than the radius of hydrated Li<sup>+</sup>.

# 9. SODIUM THIOSULFATE $(Na_2S_2O_3) 5H_2O$

Sodium thiosulfate is a salt of an unstable acid  $H_2S_2O_3$  (Thiosulphuric acid)

#### Preparation

(i) sodium sulfite and flowers of S

$$\underset{\text{soluble}}{\text{Na}_2\text{SO}_3} + \underset{\text{Insoluble}}{\text{S}} \rightarrow \text{Na}_2\text{S}_2\text{O}_3$$

(ii) Spring's Reaction

$$Na_2S + I_2Na_2SO_3 \rightarrow Na_2S_2O_3 + 2NaI$$

(iii) sodium carbonate solution with  $SO_2$ 

$$Na_2S + Na_2CO_3 + SO_2 \rightarrow Na_2S_2O_3 + CO_2 \downarrow$$

(iv) sulfur and caustic soda

$$4S + 6NaOH \xrightarrow{\Lambda} Na_2S_2O_3 + 2Na_2S + 2H_2O$$

With excess pentasulfide forms

$$Na_2S + 4S \rightarrow Na_2S_5$$

#### **Chemical Properties**

(i) Heating effect -  $Na_2S_2O_3 \cdot 5H_2O \xrightarrow{215 \circ C} Na_2S_2O_3 + 5H_2O$ 

$$4Na_2S_2O_3 \xrightarrow{223^{\circ}C} 3Na_2SO_4 + Na_2S_5$$

(ii) Acidification – Liberates SO<sub>2</sub> and S ppt.

$$Na_{2}S_{2}O_{2} + dil.2HCI \rightarrow 2NaCI + SO_{2} + S \downarrow +H_{2}O$$

$$Na_2S_2O_3 + dilH_2SO_4 \rightarrow Na_2SO_4 + SO_2 + S \downarrow + H_2O_2$$

(iii) Reduction - 
$$Na_2S_2O_3 + Cl_2 + H_2O \rightarrow Na_2SO_4 + 2HCl + S$$

$$2Na_{2}S_{2}O_{3} + 2FeCl_{3} \rightarrow 2Na\left[Fe\left(S_{2}O_{3}\right)_{2}\right] + 3Nacl_{3}$$

 $\downarrow$  (Purple)

FeCl, (green)

(iv) Oxidation - (oxidises by  $I_2$  quantitatively)

 $2Na_2S_2O_3+I_2\rightarrow 2NaI+Na_2S_4O_6$ 

 $\operatorname{sodium}$ 

tetrathionate

(v) AgNO<sub>3</sub> action -  $2AgNO_3 + Na_2S_2O_3 \rightarrow Ag_2S_2O_3 + 2NaNO_3$ 

 $Ag_2S_2O_3 + H_2O \rightarrow Ag_2S + H_2SO_4$ 

Thus white ppt. of silver thiosulfate changes as

White  $\rightarrow$  yellow  $\rightarrow$  brown  $\rightarrow$  black

(vi) Silver halide action

$$AgBr + 2Na_2S_2O_3 \rightarrow Na_3[Ag(S_2O_3)_2] + NaBr$$

sodium argento

thiosulfate(colourless)

this property is used in photography fixing.

(vii) Action on CusO<sub>4</sub>

 $CuSO_4 + Na_2S_2O_3 \rightarrow CuS_2O_3 + Na_2SO_4$ 

cupric

thiosulfate

 $CuS_2O_3 + Na_2S_2O_3 \rightarrow Cu_2S_2O_3 + Na_2S_4O_6$ 

cuprous sodium tetra thiosulfate thionate

$$Cu_{2}S_{2}O_{3} + Na_{2}S_{2}O_{3} \xrightarrow{\text{onexcess}} Na_{4} \Big[ Cu_{6} \big(S_{2}O_{3}\big)_{5} \Big]$$

sodium cupro thiosulfate(sol)

#### 10. SODIUM BICARBONATE (NaHCO<sub>3</sub>)

**Preparation**: Sodium bicarbonate is prepared by the solvay process. It is infact formed in between the manafacture of washing sodaeer

- Aqueous solution gives no colour with phenolphthalein but yellow colour with Metyl orange and hence is weakly basic.
- (ii)  $2NaHCO_3 \xrightarrow{} Na_2CO_3 + CO_2 + H_2O$
- (iii) Salts which give basic carbonates with washing soda give normal salts with the bicarbonate.

 $ZnSO_4 + 2NaHCO_3 \rightarrow ZnCO_3 + Na_2SO_4 + H_2O + 2CO_2$ 

(iv) It is used as "SODA BICARB" to neutralisc stomach acidity.

- (v) Sodium/Potassium salt of tartaric acid and NaHCO<sub>3</sub> mixture is used as Baking Soda.
- Ex. Based on lattice energhy and other considerations which one of the following alkali metal chlorides is expected to have the highest melting point

(A) LiCl (B) NaCl (C) KCl (D) RbCl

Ans. (B)

Sol. Although lattice energy of LiCl higher than NaCl but LiCl is covalent in nature and NaCl ionic there, after the melting point decreases as we move NaCl because the lattice energy decreases as a size of alkali metal atom increases (lattice energy ∞ melting point of alkali metal halide)

| Ex.  | NaOH is prepared by the method        |   |                                     |  |  |  |

# **POTASSIUM**

# Potassium and its compounds

- 1. Atomic Number : 19
- 2. Electronic Configuration : 2, 8, 8, 1
- **3.** Valency and Oxidation state: + 1
- Occurrence : Potassium is highly reactive metal. It does not occur in nature in free form It important minerals are:
   (a) Pearl ash, K<sub>2</sub>CO<sub>3</sub>
   (b) Sylvine, KCl.
   (c) Indian Salt petre, KNO<sub>3</sub>
   (d) Carnallite, KCl MgCl<sub>2</sub>. 6H<sub>2</sub>O
- 5. **Extraction** : It may be prepared by any of the following methods:
  - (a) By electrolysis of fused potassium cyanide
  - (b) by heating potassium fluoride with calcium.
  - (c) By heating potassium carbonate with carbon (coke)
  - (d) By electrolysis of molten KCl containing a little KF.

#### 6. **Properties**

- (a) Potassium is a silvery white metal (M.P.  $65^{\circ}$ ).
- (b) It is lighter and softer than sodium. It resembles sodium in its chemical properties, but is more reactive than it.
- (c) Potassium decomposes cold water more vigorously than sodium. The heat of reaction is so high that the hydrogen gas evolved catches fire when excess of metal is burnt in air or oxygen under reduced pressure, K<sub>2</sub>O is formed. When heated in excess of air, potassium forms superoxide (KO<sub>2</sub>)
- (d) Potassium (40) is feebly radioactive. It is a β-emitter. It has 3 isotopes of mass 39, 40 and 41 of which the first one is present in larger proprtions. The radioactivity is due to the presence of isotope of mass number 40 which makes up about 0.012% of the metal.

# 7. Uses

(a) Potassium is used in photoelectric cell.

- (b) An alloy of sodium and potassium which is liquid is used in high temperature thermometers.
- (i) Oxides of potassium

|         | K <sub>2</sub> O, | K <sub>2</sub> O <sub>2</sub> , | K <sub>2</sub> O <sub>3</sub> , | KO <sub>2</sub> | and | KO₃          |
|---------|-------------------|---------------------------------|---------------------------------|-----------------|-----|--------------|
| Colours | White             | White                           | Red                             | Bright Yellow   |     | Orange Solid |

# Preparation

(i) 
$$2KNO_3 + 10K \xrightarrow{\text{beating}} 6K_2O + N_2$$

 $K_2O \xrightarrow{\text{heating}} K_2O$ 

(White (Yellow)

 $K_2O + H_2O \rightarrow 2KOH$ 

(ii) 
$$2K + O_2 \xrightarrow{Controlled} K_2O_2 [Pr ops : Similar with Na_2O_2]$$

(iii) Passage of  $O_2$  through a blue solution of K in liquid  $NH_3$  yields oxides  $K_2O_2$  (white),  $K_2O_3$  (red), and  $KO_2$  (deep yellow) i.e.

K in liq. 
$$NH_3 \xrightarrow{O_2} K_2O_3 \rightarrow K_2O_3 \rightarrow KO_2$$
  
white red yellow

 $\mathrm{KO}_{2}$  reacts with  $\mathrm{H}_{2}\mathrm{O}$  and produces  $\mathrm{H}_{2}\mathrm{O}_{2}$  and  $\mathrm{O}_{2}$  both

$$2\mathrm{KO}_2 + 2\mathrm{H}_2\mathrm{O} \xrightarrow{-0^\circ\mathrm{C}} 2\mathrm{KOH} + \mathrm{H}_2\mathrm{O}_2 + \mathrm{O}_2$$

$$\mathrm{KO}_{3}: \qquad \underset{(\mathrm{Dry \, powdered})}{\mathsf{KOH}} \qquad + \qquad \mathrm{O}_{3}\left( \mathsf{ozonised oxygen} \right) \xrightarrow{-10^{\circ} \mathrm{to} - 15^{\circ} \mathrm{C}} \qquad \underset{(\mathrm{Orange \, solid})}{\mathsf{KO}_{3}}$$

# (ii) Potassium hydroxide (Caustic Potash) KOH

**Preparation**: It may be prepared like that of NaOh, i.e. the electrolysis of KCl solution and by the action of line on potassium carbonate. It may also be obtained by the action of baryta Ba(OH), on potassium sulphate

$$K_2SO_4Ba(OH)_2 \rightarrow BaSO_4 \downarrow +2KOH$$

**Properties:** Its properties are similar to those of sodium hydroxide. However, it is a stroger alkali and more soluble in alcohol and is therefore, used in organic reactions instead of caustic soda. Moreover, it is a better absorber of  $CO_2$  than NaOH because potassijm carbonate is more soluble and does not separate out. Its aqueous solution is known as potash lye.

(iii) Potassium carbonate (K,CO<sub>3</sub>) : It is also known as pearl ash.

**Preparation**: It is made by passing  $CO_2$  into a conc. solution of the chloride, containing hydrated magnesium carbonate in suspension at 20°C when an insoluble potassium hydrogen magnesim carbonate is precipitated.

$$2\text{KCl} + 3(\text{MgCO}_3.3\text{H}_2\text{O}) + \text{CO}_2 \rightarrow 2(\text{MgCO}_3.\text{KHCO}_34\text{H}_2\text{O}) + \text{MgCl}_2$$

The precipitate is separated by fitration, and then decomposed either by heating with water under pressure at 140°C or by the action of magnesium oxide below 20°C.

$$2(MgCO_{3} \cdot KHCO_{3} \cdot 4H_{2}O) \rightarrow 2MgCO_{3} + K_{2}CO_{3} + 9H_{2}O + CO_{2}$$
$$2(MgCO_{3} \cdot KHCO_{3} \cdot 4H_{2}O) + MgO \rightarrow 3(MgCO_{3} \cdot 3H_{2}O) + K_{2}CO_{2}$$

#### **Properties**

(i) It is white, deliquesent solid

(ii)  $K_2CO_3$  resembles  $Na_2CO_3$  in properties, but is more alkaline and more soluble than  $Na_2CO_3$ 

# (iv) Potassim Bicarbonate (KHCO<sub>3</sub>)

**Preparation** : It resembles sodium bicarbonate in all respects except that it is more soluble in water. It used in medicine and in baking powders.

(v) Potassium Sulphate  $(K_2SO_4)$ 

#### Preparation

(i) By treating Kcl or KOH with  $H_2SO_4$ 

$$2\mathsf{KCI} + \mathsf{H}_2\mathsf{SO}_4 \rightarrow \mathsf{K}_2\mathsf{SO}_4 + 2\mathsf{HCI}$$
$$2\mathsf{KOH} + \mathsf{H}_2\mathsf{SO}_4 \rightarrow \mathsf{K}_2\mathsf{SO}_4 + 2\mathsf{H}_2\mathsf{O}$$

(ii) By treating naturally occurring mineral, schonite  $(K_2SO_4 \cdot MgSO_4 \cdot 6H_2O)$  with sylvine (KCl)

 $K_2SO_4.MgSO_46H_2O + 2KCI \rightarrow 2K_2SO_4 + MgCl_26H_2O$ 

#### **Properties**

(i) It is a white crystalline (m.p. 1050°C) solid, not very soluble in water.

(ii) Unlike sodium sulphate, its crystals do not contain water of crystallisation.

(iii) When heated with carbon, it is reduced to potassim sulphide.

(iv) It forms a series of double salts with the sulphates of trivalent metals, e.g. potash alum,

 $K_2SO_4Al_2(SO_4)_3.24H_2O$ 

#### (vi) Potassium Chloride (KCl)

Preparation: KCl is prepared from fused carnallite. Nearly pure KCl separates from the melt, leaving fused MgCl<sub>2</sub> behing.

 $\text{KCI.MgCl}_2\text{6H}_2\text{O} \rightarrow \text{KCI} + \text{MgCl}_2\text{6H}_2\text{O}$ 

Properties: It is a colourles cubic crystal soluble in water. Its solubility increases almost linearly with temperature.

# **ALKALINE EARTH METAL**

#### **Physical state**

- (a) Two electrons in outer most shell & General formula ns<sup>2</sup>.
- (b) Radium is radioactive element
- (c) All are greyish white.
- (d) These metals are harder than alkali metals.
- (e) These are diamagnetic and colourless in form of ions or in metal states.

# Atomic size

Smaller than IA group elements, since extra charge on nucleus attracts the electron clud.

- (a) Size increases gradually from Be to Ba
- $Be\!<\!Mg\!<\!Ca\!<\!Sr\!<\!Ba$
- (b) In s-block elements
- Be is the smallest, Cs is the biggest

#### Softness

- (a) These metals are slightly harder than [A group because of -
- (i) Smaller atomic size
- (ii) FCC, HCP crystal structures
- (iii) Packing capacity 74%
- (iv) Stronger metallic bond due to presence of two electrons in valence shell.
- (b) Be is the hardest metal in s-block.

# Melting point and boiling point

- (a) Metallic bond is stronger than IA group due to smaller atomic size and two electrons in valence shell hence melting point and boiling point are higher.
- (b) Decreasing order of melting point and boiling point is

Be > Ca > Sr > Ba > Mg

(c) Melting point and Boiling point of Ca, Sr and Ba is higher than Mg because of presence of d-orbitals in the outer most shell, which forms stronger metallic bond.

#### Electro positive character or metallic character

Their atomic size is smaller than IA group so these are lesser electro positive than IA group. Electropositivity increases from Be to Ba

# **Flame Test**

(a) Be and Mg atoms, due to small size, bind their electrons more strongly, so are not excited to higher level, hence no flame test.

(b) Other delements gives characteristic colour to flame

Ca-Brick red Sr-crimson red Ba-Apple green

#### **Reaction With NH**,

(a) On increasing metal ion concentrate solution converts into bronze colour due to cluster formation of metal ions.(b) Solubility in liquid ammonia

(i) Only Ca, Sr and Ba gives blue solution of ammoniated electron.

(ii) Be and Mg are small in size and have high ionisation potential so do not dissolves in liquid NH<sub>2</sub>.

(iii) Dark blue colour of solution becomes fade if it allowed to stand for a long time, it is because of metal amide formation.

(iv) Blue colour of solution disappears on addition of of ammonium salt, due to NH<sub>3</sub> formation

 $NH_4^+ + NH_2^- \rightarrow 2NH_3$ 

#### **Photo Electric Effect**

These elements do not show this property as their atomic size is small hence ionisation potential is higher than IA group.

#### **Standard oxidation potential**

(a) They have lower values of standard oxidation potential due to their small size

(b) Increasing order of standard oxidation potential is

Be < Mg < Ca < Sr < Ba

(c) Tendendy of loosing electron increases

#### Hydration energy (heat of hydration)

- (a) Due to smaller ionic sixe and higher charge density their hydroation energy is high
- (b) Its decreasing order is

 $Be^{+2} > Mg^{+2} > Ca^{+2} > Sr^{+2} > Ba^{+2}$ 

(c) hydration energy  $\propto 1/cation$  size

#### **Reducing property**

- (a) Less reductant than alkali metals
- (b) Order of reducing property in aqueous and gasesouts medium is

 $Be^{^{+2}} < Mg^{^{+2}} < Ca^{^{+2}} < Sr^{^{+2}} < Ba^{^{+2}}$ 

# **Reaction with AIR**

(a) Except Be, these metals are easily turnished in air, as a Layer of oxide is formed on the surface.

(b) Barium in powdered from, burst into flame on exposure to air.

(c) In moist air, except Be all the elements converts into carbonates.

(d) In dry air Be and Mg gives nitride and oxide both while other gives only oxides.

# **Reactivon with oxygen**

(a) Alkaline earth metals reacts with O<sub>2</sub> to form 'MO' Type oxides

(M = Be, Mg, Ca, Sr, Ba)

(b) But Ca, Sr and Ba due to low ionisation potential and more reactivity, forms MO<sub>2</sub> (peroxides) at low temperature.

Ex. CaO<sub>2</sub>, SrO<sub>2</sub>, BaO<sub>2</sub>

(c) Peroxides are coloured due to Lattice deffect.

(d) BeO shows amphoteric property.

Mgo  $\rightarrow$  weak base

CaO, SrO & BaO  $\rightarrow$  Strong base

(e) Basic properties increases from Be to Ba

(f) Its stability order general oxide > Peroxide > super oxide

# **Reaction with water**

(a) These metals reacts slowly with water gives  $H_2$  and metals hydroxides

 $M + 2H_2O \rightarrow M(OH)_2 + H_2$ 

(b) Be does not reacts with water

(c) Mg reacts only with hot water

(d) Ca, Sr, Ba reacts with cold water but not as energetically as alkali metals, order of reactivity

Ba > Sr > Ca > Mg > Be

(e) From Be(OH), to Ba(OH), basic property and stability increases.

#### Halides

(a) Alkaline metals reacts with X (Halogen) to form MX<sub>2</sub>.

- **Ex.**  $(BeCl_2, MgCl_2, CaCl_2 etc.)$
- (b) Ionic nature of MX, increases from BeCl<sub>2</sub> to BaCl<sub>2</sub>
- (c) Ba burns in contact with Cl,
- (d) Hydrolytic nature of these halides decreases from BeCl<sub>2</sub> to BaCl<sub>2</sub>
- (e) BeCl<sub>2</sub> and MgCl<sub>2</sub> are covalent in nature. Order of ionic nature

 $BeCl_2 < MgCl_2 < CaCl_2 < SrCl_2 < BaCl_2$ 

Solubility in water

 $BeCl_2 > MgCl_2 > CaCl_2 > SrCl_2 > BaCl_2$ 

# Carbonates

- (a) All the alkaline metals froms MCO<sub>3</sub> type carbonates
- (b) Except  $BeCO_3$ , all the carbonates are stable towards heat

 $BeCO_3 \longrightarrow BeO + CO_2$ 

(c) Order of decreasing stability

 $BaCO_3 > SrCO_3 > CaCO_3 > MgCO_3 > BeCO_3$ 

# Nitrates

(a) Alkaline earth metals forms  $M(NO_3)_2$  type nitrates. (M – Alkaline earth metal).

(b) Stability increases from  $Be(NO_3)_2$  to  $Ba(NO_3)_2$  but these are less stable than IA group, due to smallear atomic size.

(c) All alkaline metals nitrates on heating gives oxides and  $NO_2 + O_2$ 

 $M(NO_3)_2 \longrightarrow Oxidw + NO_2 + O_2$ 

(d)  $Be(NO_3)_2$  forms a layer of BeO on its surface so reaction stops.

#### Nitrides

Only Be and Mg burns in N<sub>2</sub> to give  $M_3N_2(Be_3N_2,Mg_3N_2)$ 

$$Be_{3}N_{2} + 6H_{2}O \rightarrow 3Be(OH)_{2} + 2NH_{3}$$

 $Mg_3N_2 + 6H_2O \rightarrow 3Mg(OH)_2 + 2NH_3$ 

# **Formation of amalgam**

Shows same properties as alkali matals.

## **Sulphates**

(a) Alkaline earth metals forms MsO<sub>4</sub> type sulphates

(b) Ionic nature of alkaline metal sulphate is increases from Be to Ba

 $BeSO_4 < MgSO_4 < CaSO_4 < SrSO_4 < BaSO_4$ 

(c) Solubility decreases from  $BeSO_4$  to  $BaSO_4$  as  $Be^{+2}$  and  $Mg^{+2}$  are of small size so their hydration energy is high Hydration energy > Lattice energy.

(d) Order of solubility -

BeSO<sub>4</sub>, MgSO<sub>4</sub>, CaSO<sub>4</sub>, SrSO<sub>4</sub>, BaSO<sub>4</sub>

Ionic nature increases, Thermal stability increases

### **Reaction with acids**

Freely reacts with acids and displaces hydrogen

 $M + 2HCI \rightarrow Mcl_2 + H_2 \uparrow$ 

# **Hydrides**

(a) Except be, all alkaline earth metals from hydrides  $(MH_3)$  on heating direcely with H<sub>2</sub>.

 $M + H_2 \rightarrow MH_2$ 

(b) BeH<sub>2</sub> is prepared by the action of LiAlH<sub>4</sub> on BeCl<sub>2</sub>

 $2\text{BeCl}_2 + \text{LiAlH}_4 \rightarrow 2\text{BeH}_2 + \text{LiCl} + \text{Alcl}_3$ 

(c)  $BeH_2$  and  $MgH_2$  are covalent while other hydrides are ionic

(d) The ionic hydrides of Ca, Sr, Ba liberated H, at anode and metal t cathode.

 $CaH_2 \xrightarrow{Fusion} Ca^{2+} + 2H^{-}$ 

(e) The stability of hydrides decreases from Be to Ba.

- (f) The hydrides having higher reactivity for water, dissolves readily and produce hydrogen gas.
- (g) The hydrides having higher reactivity for water, dissolves readily and produce hydrogen gas.

$$CaH_2(s) + 2H_2O \rightarrow Va(OH)_2 + 2H_2 \uparrow$$

**Carbides :** BeO when heated with C at about 2000°C,  $Be_2C$  is formed. The metals Mg, Ca, Sr and Ba form carbides for the formula MC<sub>2</sub>. These carbides are formed when the metal or the metal oxide is beated with carbon in an electric fumace.

These carbides are ionic in nature.

Be<sub>2</sub>C yields methane on hydrolysis whereas carbides of other metals yield acetylene

$$\operatorname{Be}_{2}\mathrm{C} + 4\mathrm{H}_{2}\mathrm{O} \rightarrow 2\mathrm{Be}(\mathrm{OH})_{2} + \mathrm{CH}_{4}$$

$$CaC_2 + 2H_2O \rightarrow Ca(OH)_2 + C_2H_2$$

**Complex compounds :** Alkaline earth metals have a tendency to form state complexes. Their ability to form complexes is more as compared to alkali meals. This is because of the smaller size and higher charge of the alkaline earth metal ions as compared to alkali metal ions. Among the elements of group-2, beryllium and magnesium, have greater tendency of complexation.

**Ex.** In alkaline earth metals, the electrons are more firmly held to the nucleus and hence

- (A) Ionization energy of alkaline earth metals is greater than that of alkali metals
- (B) Alkaline earths are less abundant in nature
- (C) Reactivity of alkaline earth metals is greater than that of alkali metals
- (D) Atoms of alkaline earth metals are bigger in size than alkali metals.
- Ans. (A)
- Sol. Ionization energies of alkaline earth metals are greater than those of alkali metals due to increased nuclear charge.
- **Ex.** The ion having highest mobility in aqueous solution is

(A)  $Be^{2+}$  (B)  $Mg^{2+}$  (C)  $Ca^{2+}$  (D)  $Ba^{2+}$ 

Ans. (D)

- Sol. Though  $Ba^{2+}$  is the heaviest ion but it is least hydrated. As a result, its size becomes lesser than any other hydrated alkaline earth metal cation and hence has the highest ionic mobility.
- **Ex.** Alkaline earth metal show typical characterics of
  - (A) Inner transition elements
  - (B) Noble gases
  - (C) Representative elements
  - (D) Transition elements
- Ans. (C)

**Ex.** Which of the following is true for magnesium ?

(A) It is more electropositive than sodium

(B) It is manufactured by electrolysis of aqueous magnesium chloride

(C) It is a strong reducing agent

(D) It resembles, in chemical properties, with its diagonally placed element Boron in 13 group of the periodic Table.

Ans. (C)

#### **EXTRACTION OF ALKALINE METALS**

#### (1) Beryllium

**Occurrence**: (1) Beryl-3Beo, Al3O<sub>2</sub>,  $6 \text{ SiO}_3$  (2) Chrysoberyl – BeO, Al<sub>2</sub>O

Extraction

The powered beryl is treated with sulphuric acid when sulphates of beryllium and aluminium are formed from which aluminium sulphate is removed double sulphate by the addition of  $(NH_4)_2 SO_4$ . Beryllium sulphate remaining solution is separated and calcined at high temperature to give BeO<sub>4</sub>. The oxide is finally reduced to the metal y heatingh with carbon.

Uses: (1) In making alloys /0 a very small quantity of Be added to Mg increases casting power

(2) It is highty permeable to X-rays and hence used for windows of x-ray tubes.

(3) In nuclear reactions as a source of neutrons, Bombarded with  $\alpha$ -particles, Beryllium gives neutrons.

$$_{4}Be^{9} + _{2}H^{4} \rightarrow _{6}C^{12} + _{0}n^{1}$$

#### (2) Magnesium

Importance ores of magnesium are

| (i) Magesite, MgCO <sub>3</sub> | (ii) Dolomite, $MaCO_3$ .CaCO <sub>3</sub> |
|---------------------------------|--|
|                                 |  |

(iii) Carnallite, KCl. MgCl.  $6H_2O$  (iv) Kieserite, MgSO<sub>4</sub>. $H_2O$ 

Sea water also contains mgnesium salts. Magnesium content in sea - water in about 0.13% Magnesium is extracted by electrolysis of a molten mixture of anhydrous  $MgCl_2$ , Nacl and  $CaCl_2$  Anhydrous  $MgCl_2$  may be obtained from sea water on from carnallite.

Anhydrous  $MgCl_2$  is prepared from hydrated  $Mgcl_2(MgCl_2.6H_2O)$  by passing a surrent of dry HCl gas over it. Anhydrous MgCl, cannot be prepared by direct heating because it results in formation of MgO which is refractory

 $MgCl_2.6H_2O \longrightarrow MgO + 2HCl + 5H_2O$ 

During electrolysis, the following reactions take place.

 $MgCl_{2}?Mg^{2+} + 2Cl^{-}$ 

At cathode :  $Mg^{2+} + 2e^{-} \rightarrow Mg$ 

At anode :  $2CI^- \rightarrow CI_2 + 2e^-$

3.

Calcium

**Ores of Calcium** 

- Ex. A piece of magnesium ribbon was heated to redness in an atmosphere of nitrogen and then cooled with water. The gas evolved is (C) Nitrogen (D) Oxygen
  - (A) Ammonia (B) Hydrogen

# **COMPOUND OF ALKALINE EARTH METALS**

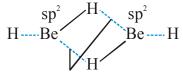

#### **Berylium** (1)

Oxides and hydroxides : Be jforms only the monoxides: all others from monoxide and peroxide (eg. BaO, BaO<sub>3</sub>). The **(i)** basic nature of the oxides and hydroxides of the metals increases down the group. BeO is amphoteric, CaO, SrO and BaO are basic. All these oxides dissolve in H<sub>2</sub>O giving the hydroxide (BeO is nearly insoluble). BeO dissolves in acids and alkalies to give salts.

 $(BeO) + 2HCI \rightarrow BeCl_2 + H_2O : BeO + 2NaOH \rightarrow Na_2BeO_2 + H_2O$  The solubility of the hydroxides increase

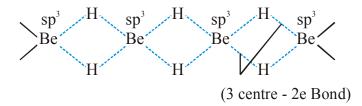

from Be to Ba.  $Ba(OH)_2$  (Baryta) is moderately soluble in water.

Hydrides :  $BeH_2$  is covalent MgH<sub>2</sub> is partially covalent and the remaining hydrides are largely ionic.  $BeH_2$  is **(ii)** polymeric solid, involving hydrogen bridging.

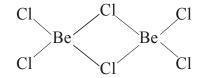

(3 centre - 2e Bond)

# Dimer form of BeH<sub>2</sub> in vapour phase

Polymeric form of BeH<sub>2</sub> in solid state

(iii) Halides: II group metal when heated with halogens, give the halides. Beryllim halides (eg. BeF, and BeCl,) are covalent due to the small size of  $Be^{2+}$  (see fajan's jrules) and hence have comparatively low melting points and boiling points. The chlorides and fluorides of the ojther metals of the group are ionic solid  $BeCl_2$  in the solid state is polymeric containing chains of the form.

In the vapour staate at high temperature BeCl, is a monomer.

The halides are deliquescent and they form jhydrated salts. The solubility of halides in water decrease down the group from Ca to Ba.

Ans. **(A)** 

(iv) Sulphates : BeSO<sub>4</sub> is slightly soluble in water. The solubility of the sulphates of the metals decreases down the group BaSO<sub>4</sub> and RaSO<sub>4</sub> are parctically insoluble.

[Note : The solubility of an ionic solid in water depends on the lattice energy of the solid and the hydrateion energy for the ions of the solid. A large value of the former would lower the solubility, gydration energy factor has a dominant role. Since the hydration of ion decreases from,  $Be^{2+}$ , to hydroxides of this group, the lattice energy has a dominant rjole and hence the solubility of these salts increases down the group.]

- (v) **Carbonates and biearbonates**: The carbonates of alkaline earth metals are insoluble in water: the bicarbonates are soluble. The carbonates and bicarbonates decompose on heating to give CO<sub>2</sub> gas.
- (vi) Carbides of II group metal are ionic carbides, which may be in a methanide or acetylide or allylide.

# **Beryllium Carbide**

Be<sub>2</sub>C (methanide) reacts with water to give methane.

 $Be_2C + 2H_2O \rightarrow 2BeO + CH_4$ 

#### **Calcium** Carbide

 $CaC_2$  (acetylide) is decomposed by  $H_2O$  to give acetylene.

 $CaC_2 + 2H_2O \rightarrow Ca(OH)_2 + C_2H_2$ 

# **Magnesium Carbide**

 $Mg_2C_3$  (allylide) reacts with water to give allylene (methyl acetylene)

 $Mg_2C_3 + 4H_2O \rightarrow 2Mg(OH)_2CH_3C \equiv CH$ 

# (vii) Nitrides

Example :  $Mg_3N_2$  decomposed by H<sub>2</sub>O liberating NH<sub>3</sub>.

 $\left[\mathsf{Mg}_{3}\mathsf{N}_{2} + 6\mathsf{H}_{2}\mathsf{O} \rightarrow \mathsf{3Mg}(\mathsf{OH})_{2} + 2\mathsf{NH}_{3}\right] \text{ Similarly } \mathsf{Ca}_{3}\mathsf{N}_{2}$ 

Complexes : Be is the best complexing agent in this group. The complexing tendency decrease down the group. Mg  $(Oxine)_2$  is the complex formed by Mg<sup>2+</sup> with 8 hydroxy quinoline(Oxine) and this forms the basis of quantitative estimation of Mg.

- Ex. A metal M redily forms water soluble sulphate  $MSO_4$  water insoluble hydroxide  $M(OH)_2$  and oxide jMO which becomes inert on heating. The hydroxide jis soluble in NaOH. The M is (A) Be (B) Mg (C) Ca (D) Sr
- Ans.
- Sol.  $Be(OH)_2$  is amphoteric in nature so it is soluble in NaOH
- Ex. Amongst the following hydroxides, the one which has the lowest value of Ksp at ordinary temperatue is :

(A) 
$$Mg(OH)_2$$
 (B)  $Ca(OH)_2$  (C)  $Ba(OH)_2$  (D)  $Be(OH)_2$ 

Ans. (D)

# (2) Magnesium

**(A)** 

Magnesium Sulphate (MgSO<sub>4</sub>, 7H<sub>2</sub>O) epsum salt
 Preparation
 From magnesite or dolomite (Epsom salt)

 $\begin{aligned} \mathsf{MgCO}_3 + \mathsf{H}_2\mathsf{SO}_4 \to \mathsf{MgSO}_4 + \mathsf{H}_2\mathsf{O} + \mathsf{CO}_2 \uparrow \\ \mathsf{MgCo}_3.\mathsf{CaCO}_3 + 2\mathsf{H}_2\mathsf{SO}_4 \to \mathsf{MgSO}_4 + \mathsf{CaSO}_4 \downarrow + 2\mathsf{H}_2\mathsf{O} + 2\mathsf{CO}_2 \end{aligned}$ 

#### **Physical properties**

Colourless, efflorescent crystalline substance which forms a number of hydrate **Chemical properties** 

On heating  $MgSO_4.7H_2O \xrightarrow{160^{\circ}C} MgSO_4.H_2O \xrightarrow{200^{\circ}C} MgSO_4 + H_2O$ 

It is reduced by lamp black

$$2MgSO_4 + C \xrightarrow{300^{\circ}C} 2MgO + 2SO_2 + CO_2 \uparrow$$

#### USES

1.  $MgSO_4$  is manufactured by dissolving keiserite ( $MgSO_4$ . $H_2O$ ) in boiling water & then cryatallising the solution.

- 2. MgSO4.7H2O is called as Eposm salt & shows deliquesecence efflorescence & has purgative action.
- 3. Platinized MgSO4 is used as catalyst in Grillo's process for manufacture of  $H_2SO_4$ .

#### (ii) Magnesium Chloride MgCl,.6H,O

Magnesium chloride can be prepared by fractional crystallization of cammallite, KCl. MgCl<sub>2</sub>.  $6H_2O$ . It can also be obtained from sea water. Magnesium salts present in sea-water are precipi tated as Mg(OH)<sub>2</sub> by adding lime. The precipitate is filtered and dissolved in HCl solution. The solution on crystallization yields crystals of MgCl<sub>2</sub>.  $6H_2O$ . It can also be

$$\begin{split} \mathsf{Mg}^{2+} + \mathsf{Ca}(\mathsf{OH})_2 &\to \mathsf{Mg}(\mathsf{OH})_2 \downarrow + \mathsf{Ca}^2 \\ \mathsf{Mg}(\mathsf{OH})_2 + 2\mathsf{HCI} \to \mathsf{MgCI}_2 + 2\mathsf{H}_2\mathsf{O} \end{split}$$

A mixture of magnesium chlorid and magnesium oxid is known as Sorel cement or magnesium cement. This mixture reacts with water and sets into a solid mass having composition

MgCl<sub>2</sub>.5MgO.xH<sub>2</sub>O

#### (iii) Magnesium Oxide (MgO)

**Preparation** : It is prepared by burning Mg in air, by heating hydroxide, nitrate, sulphate or carbonate. Oxide prepared by heating magnesite (MgCO<sub>3</sub>) is called calcined magnesia.

$$2Mg(NO_3)_2 \rightarrow 2MgO + 4NO_2 + O_2$$
$$2MgSO_4 \rightarrow 2MgO + 2SO_2 + O_2$$

#### **Properties**

(i) Magnesium oxide is a light white powder, which is highly infusible (m.p. 2800°C), and only slightly soluble in water.

(ii) It is a basic oxide and hence reacts with acids to form salts.

 $MgO + 2HCI \rightarrow MgCl_2 + H_2O$ 

(iii) It is reduced by carbon at very high temperature to form magnesium carbide.

$$MgO + 3C \rightarrow MgC_2 + CO$$

(iv) It dissolves in aqueous solution of magnesium chloride or bromide forming basic salts such as MgCl<sub>2</sub>.9Mg(OH)<sub>2</sub>.5H<sub>2</sub>O.

#### (iv) Magnesium Hydroxide (Mg(OH),)

Preparation : It is obtained by adding caustic soda solution to a solution of magnesium sulphate or chloride.

$$MgSO_4 + 2NaOH \rightarrow Na_2SO_4 + Mg(OH)_2$$

#### Properties

(i) It is converted into its oxide on heating.

 $Mg(OH)_2 \rightarrow MgO + H_2O$ 

(ii) It dissolves in NH4CL solution easily.

$$Mg(OH)_2 + 2NH_4CI \rightarrow MgCl_2 + 2NH_4OH$$

(v) Magnesium Carbonate, (MgCO<sub>3</sub>): It occurs in nature as magnesite, MgCO<sub>3</sub> and dolomite, MgCO<sub>3</sub>.CaCO<sub>3</sub>.

(i) By adding sodium bicarbonate solution to a hot solution of magnesium salt.

$$MgSO_4 + 2NaHCO_3 \rightarrow MgCO_3 \downarrow + Na_2SO_4 + H_2O + CO_2$$

In case Na<sub>2</sub>CO<sub>3</sub> is used in place of NaHCO<sub>3</sub>, a basic carbonate is obtained.

$$2MgSO_4 + 2Na_2CO_3 + H_2O \rightarrow MgCo_3.Mg(OH)_2 + 2Na_2SO_4 + CO_2$$

When  $CO_2$  gas is passed through the suspension of basic carbonate, magnesium bicarbonate is formed which on heating forms MgCO<sub>3</sub>.

$$MgCO_{3}.Mg(OH)_{2} + 3CO_{2} + H_{2}O \rightarrow 2Mg(HCO_{3})_{2}$$
$$Mg(HCO_{3})_{2} \xrightarrow{\text{heat}} MgCO_{3} + H_{2}O + CO_{2} \uparrow$$

(ii) Pure magnesium bicarbonate and hence carbonate can be prepared by passing  $CO_2$  through suspension of magnesium oxide in water.

$$MgO + H_2O + 2CO_2 \rightarrow Mg(HCO_3)_2$$
$$Mg(HCO_3)_2 + MgO \rightarrow 2MgCO_3 + H_2O$$

#### **Properties**

(i) Magnesium carbonate is a white powder, insoluble in water.

(ii) It dissolves in acids forming salts.

$$MgCO_3 + 2HCI \rightarrow MgCI_2 + H_2O + CO_2 \uparrow$$

(iii) Its aqueous solution also dissolves on passing a current of carbon dioxide because of the formation of  $Mg(HCO_3)_{22}$ , a temporary hardness causing substance.

$$MgCO_3 + H_2O + CO_2 \rightarrow Mg(HCO)_3)_2$$

A solution of magnesium bicarbonate containing 12 gm. of the salt per 100 ml is known as fluid magnesia. (iv) It decomposes on heating to form magnesium oxide.

 $MgCO_3 \xrightarrow{heat} MgO + CO_2$ 

#### 6. Sorel cement

Magnesium oxide when mixed with a saturated solution of magnesium chloride sets to a hard mass like cement known as magnesia cement or Soral cement. The composition is

MgCl<sub>2</sub>.5MgO.xH<sub>2</sub>O Mg(ClO<sub>4</sub>), is known as anhydrone

| Ex.  | Magnesium burns in CO <sub>2</sub> to form  |                 |                       |        |  |  |  |

|             | Means it is an exothermic reac  | tion.                   |                |                        |  |  |  |

#### **Properties**

(i) Sparingly soluble in water and its solubility decreases with increases in temperature.

(ii) Action of  $\text{CO}_2$  : Lime water turns milky on passing  $\text{CO}_2$  gas

 $Ca(OH)_2 + CO_2 \rightarrow CaCO_3 + H_2O$ (Milkiness)

#### (iii) Action of chlorine

(a) Cold Condition :

 $2Ca(OH)_2 + 2CI_2 \xrightarrow{Cold} CaCI_2 + Ca(OCI)_2 + 2H_2O$ 

(Cal. hypochlorite)

(b) Below 35°:  $3Ca(OH)_2 + 2CI_2 \xrightarrow{below} CaOCI_2 + H_2O$ 

(c) On gentle Heating :  $6Ca(OH)_2 + 6cl_2 \xrightarrow{\text{Heat}} 5CaOCl_2 + H_2O$ 

(d) On Red Hot :

$$2Ca(OH)_{2} + 2CI_{2} \xrightarrow{\text{RedHeat}} 2CaCI_{2} + Ca(CIO_{3})_{2} + 6H_{2}O$$

(iv) Action of Ammonia

$$Ca(OH)_{2} + 2NH_{4}CI \longrightarrow CaCI_{2} + 2NH_{3} + 6H_{2}O$$

Uses

(i) For softening of hard water.

(ii) For purification of sugar and coal gas

- (iii) In preparation of bleaching powder, white wash, plaster etc.
- (iii) Calciium Carbonate, (CaCO<sub>3</sub>): Calcium carbonate is found in nature as limestone, marble, coral ice land spar, calcite, chalk, dolomitc, etc.

**Preparation:** It is prepared as a white powder, known as precipitated chalk by dissolving marble or limestone in hydrochloric acid followed by precipitation with sod. or ammonium carbonate.

 $CaCO_{3}2HCI \rightarrow CaCI_{2} + H_{2}O + CO_{2}$ 

$$CaCl_{2} + (NH_{4})_{2}CO_{3} \rightarrow CaCO_{3} + 2NH_{4}Cl_{3}$$

In the laboratory, it is prepared by passing  $CO_2$  through lime-water or by adding sod. or ammo carbonate solution of CaCl<sub>2</sub>.

$$Ca(OH)_2 + CO, \rightarrow CaCO_3 \downarrow +H_2O$$

#### **Properties**

(i) It is a white powder and exists in two crystalline forms: calcite and aragonite.

(ii) It is insoluble in water but dissolves in the presence of CO<sub>2</sub> due to the formation of calcium bicarbonate.

$$CaCO_3 + H_2O + CO_2 \rightarrow Ca(HCO_3)_2$$

(iv) Calcium Bicarbonate,  $(Ca(HCO_3)_2)$ : It does not exist in solid state. however, its solution can be prepared by passing CO<sub>2</sub> gas through a suspension of calcium carbonate in water. On warm ing, it decomposes to calcium carbonate along with the evolution of carbon dioxide gas.

(v) Calcium Sulphate, (CaSO<sub>4</sub>): It occurs in nature as anhydride (CaSO<sub>4</sub>) and gypsum (CaSO<sub>4</sub>·2H<sub>2</sub>O)

Preparation: It may be prepared by adding dilute sulphuric acid or soluble sulphate (e.g.  $Na_2SO_4$ ) to the solution of a calcium salt.

$$CaCl_2 + H_2SO_4 \rightarrow CaSO_4 + 2HCI$$

#### **Properties**

- (i) It is a white crystalline solid. Like slaked line it is sparingly soluble in cold water and its solubility decreases further with the increase in temperature.
- (ii) In dissolves much more readiluy in dilute acids, even in acetic acid than in water. It dissolves also in ammonium sulphate solution forming  $CaSO_4$ .(NH<sub>4</sub>)SO<sub>4</sub>H<sub>2</sub>O
- (iii) Monoclinic crystals of gypsum when heated, first changes into orthorthombic form without any loss of water. On further heating to 120°C, it loses three-fourth of its of crystallization and forms the hemihydrate,

$$(2CaSO_4).H_2O \text{ or } CaSO_4.\frac{1}{2}H_2O + 1\frac{1}{2}H_2O$$

Plaster of paris is a white powder which when mixed with water takes up to water of crystallization again, thus converted back into the dehydrate and sets to a hard mass with slight expansion. Setting takes about 10–15 minutes and may be catalysed by the addition of common salt or delayed by the use of alum or borax.

$$\begin{array}{c} CaSO_{4} \cdot \frac{1}{2}H_{2}O \xrightarrow[]{H_{2}O} \xrightarrow[]{Baster of paris} CaSO_{4} \cdot 2H_{2}O \xrightarrow[]{Ardening} \xrightarrow[]{Ardening} CaSO_{4} \cdot 2H_{2}O \xrightarrow[]{Monochlinic(gypsum)} \xrightarrow[]{Baster of paris} CaSO_{4} \cdot 2H_{2}O \xrightarrow[]{Monochlinic(gypsum)} \xrightarrow[]{Baster of paris} CaSO_{4} \cdot 2H_{2}O \xrightarrow[]{Ardening} \xrightarrow[]{Baster of paris} CaSO_{4} \cdot 2H_{2}O \xrightarrow[]{Baster of paris} \xrightarrow[]{Bastero of paris} \xrightarrow[]{Bastero of paris} \xrightarrow[]{Bastero of paris} \xrightarrow[]{Ba$$

Plaster of paris of gypsum when heated to about 200°C is converted into anhydrous calcium sulphate. The anhydrous from (anhydrite) is known as dead burnt because it does not set like Plaster of Paris when moistened with water.

#### (vi) Calcium Chloride (CaCl<sub>2</sub>)

Preparation: It separates out as deliquesent crystals when a solution of lime or calcium carbonate in HCl is evaporated.

$$CaCO_32HCL \rightarrow CaCl_2 + H_2CO_3$$

But is separates out from the reaction mixture as  $CaCl_2.6H_2O$ . The anhydrous salt is obtained on heating above 200°C.

Properties : It is a colourless, deliquescent salt, highly soluble in water. The anhydrous salt is an excellent drying agen.

#### (vii) Superphosphate

Phosphate rocks such as fluoroaptatie  $[3Ca_3(PO_4)_2.CaF_2]$  are very insoluble, and thus are of no use to plants.

Superphosphate is made by treating phosphate rock with concentrated  $H_2SO_4$ . The acid salt  $Ca(H_2PO_4)_2$  is more soluble, and over a period of weeks the superophosphate will dissolve in the solid water.

$$[3(Ca(PO_{4})_{2}.CaF_{2}] + 7H_{2}SO_{4} \rightarrow 3Ca(H_{2}PO_{4})_{2} + 7CaSO_{4} + 2HF$$

#### Superphosphate

"Triple superphosphate' is made in similar way, using  $H_3PO_4$  to avoid the formation of the waster product CaSO<sub>4</sub>

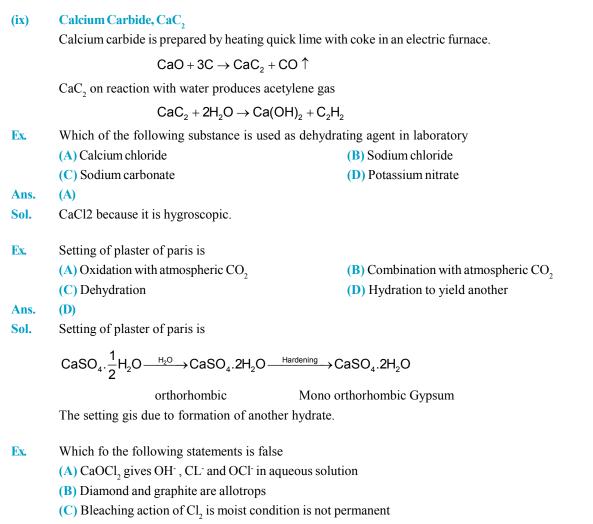

$$[3(Ca(PO_4)_2.CaF_2] + 14H_3PO_4 \rightarrow 10Ca(H_2PO_4)_2 + 2HF_4)$$

# triple superphosphate

#### (viii) Hydrolith

CaH, is technically called hydrolith and use on large scale for the production of hydrogen

$$CaH_2 + 2H_2O \rightarrow Ca(OH)_2 + 2H_2$$

```
Ans. (C)
```

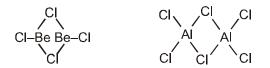

# SIMILARITIES BETWEEN LITHIUM AND MAGNESIUM

- (a) Both lithlum and magnesium are harder and lighter than other elements in the respective groups.
- (b) Lithium and magnesium react slowly with cold water. Their oxides and hydroxides are much less soluble and their hydroxides decompose on heating. Both form a nitride by direct combination with nitrogen,  $Li_3N$  and  $MgN_2$ .
- (c) The oxides,  $Li_2O$  and MgO do not combine with excess oxygen to give a peroxide or a super oxide.
- (d) The carbonates of lithium and magnesium decompose easily on heating to form the oxide and  $CO_2$ . Solid bicarbonates are not formed by lithium and magnesium.
- (e) Both LiCl and MgCl, are soluble in ethanol.
- (f) Both LiCl and MgCl<sub>2</sub> are deliquescent and crystallise from aqueous solution as hydrates, LiCl.2H<sub>2</sub>O and MgCl<sub>2</sub>.8H<sub>2</sub>O.

#### DIAGONAL SIMILARITY BETWEEN BERYLLIUM AND ALUMINIUM

In many of its properties, beryllium resembles aluminium. Thus-

- (a) The two elements have same electronegativity and their charge / radius ratios.
- (b) Both metals are fairly resistant to the action of acids due to a protective film of oxide on the surface. Both metals are acted upon by strong alkalies to form soluble complexes, beryllates  $[Be(OH)_4]^2$  and aluminates,  $[Al(OH)_4]^2$ .
- (c) The chlorides of both beryllium and aluminium

have bridged chloride structures in vapour phase.

(d) Salts of these metals form hydrated ions, Ex.  $[Be(OH_2)_4]^{2+}$  and  $[Al(OH_2)_6]^{3+}$  in aqueous solutions. Due to similar charge/ radius ratios of beryllium and aluminium ions have strong ten dency to form complexes. For example beryllium forms tetrahedral complexes such as  $BeF_4^{2-}$  and  $[Be(C_2O_4)_2]^{2-}$  and aluminium forms octahedral complexes like  $AlF_6^{3-}$  and  $[Al(C_2O_4)_3]^{3-}$
